CONTENTS

Preface		lii
Chapter 1	Adolescent Alcohol Misuse.....	1
	Donald E. Greydanus, Mohammed Morad and Joav Merrick	
Chapter 2	The Impact of Exposure to Alcohol Advertisements on Adolescents: A Literature Review.....	7
	Marye Margaret Boggs and Praveen Durgampudi	
Chapter 3	Alcohol-Related Road Traffic Accidents in the English-Speaking Caribbean: A Call to Action.....	21
	Tara Francis, Brian Fremaux, Nequella George, Lydia Atkins and Ezinwanneamaka M. Ejiofor	
Chapter 4	The Relationship between Alcohol Use and Social and Cultural Determinants in Grenadian Adolescents	31
	Alisha Francis, Cecilia Hegamin-Younger and Christine Richards	
Chapter 5	Alcohol Misuse in Adulthood Following Experiences of Psychological Maltreatment during Childhood	43
	Samantha Longman-Mills and Carole Mitchell	
Chapter 6	Gender and Suicidal Behaviour among Adolescents Who Use Alcohol.....	53
	Toni Heron, Roger Gibson, Patrice Whitehorne-Smith and Wendel Abel	
Chapter 7	The Jamaican Secondary School Survey: Parental Influences Associated with Adolescent Alcohol Use.....	63
	Eulalee M. A. Thompson, Uki Atkinson, Patrice Whitehorn-Smith, Pernell Clark, Roger Gibson and Wendel D. Abel	

Chapter 8	Smashing Babash: An Evaluation of Unregulated Rum in Grenada.....	75
	Cecilia Hegamin-Younger, Alexander Plochocki, Nakul Chopra, Praveen Durgampudi, Faisal Husain and Adbul Seckam	
Chapter 9	Influential Factors Affecting Underage Drinking among Caribbean Youths.....	83
	Nikita Cudjoe, Emmanuel Keku, Cecilia Hegamin-Younger and Shelly Rodrigo	
Chapter 10	How Many Drinks Has Your Adolescent Been Offered Today?	95
	Cecilia Hegamin-Younger, Rohan Jeremiah, Marye Boggs, Michelle Corpuz, Danielle Torres, Anne Mbari, Antonia Stanislaus, Birtukan Ejigu and Tessa St. Cyr	
Chapter 11	Alcohol and Aviation: An Assessment of Aeronautical Decision Making among Caribbean Pilots.....	105
	Satesh Bidaisee and Darren Dookeeram	
Chapter 12	Assessment of Health-Compromising Behavior Prevalence and Clustering among Grenadian Adolescents: Findings from the 2008 Global School-Based Student Health Survey.....	115
	Kim Oelhafen, Brian Shayota and Cecilia Hegamin-Younger	
Chapter 13	Drug Consumption in Suriname: Influence of Knowledge of Consequences and Academic Performance	125
	Josephine Gathura and Sherif Abdoelrahmen	
Chapter 14	Community Engagement: A Commentary on Promoting the Health of Communities	133
	I. Leslie Rubin, Courtney G. Flint, Melanie Pearson, Veda Johnson and Carol J. Rowland Hogue	
Chapter 15	Mommy: A Maternal Health Surveillance System	153
	Julia C. A. Chaves, Enrique Cifuentes and Alessandra A. Macedo	
Chapter 16	Disparities in Access to Early Intervention Services for Extremely Preterm Infants by Family Income.....	163
	Marie L. Fefferman, Bree L. Andrews and Michael E. Msall	
Chapter 17	An Ecological Model of Health Care Access Disparities for Children.....	179
	Xiaoxin Kuang, Kiana R. Johnson, Karen Schetzina, Claudia Kozinetz and David L. Wood	

Chapter 18	Grandparents Raising Grandchildren with Disabilities: Assessing Health Status, Home Environment and Impact of a Family Support Case Management Model.....	193
	Kelly Brown, Victoria Churchill, Elham Laghaie, Fatima Ali, Shaaz Fareed and Lilly Immergluck	
Chapter 19	Addressing Social Determinants of Health at a Federally Qualified Health Center.....	203
	Caroline Hensley, Avinash Joseph, Shivam Shah, Christy O'Dea and Kelley Carameli	
Chapter 20	Health Vulnerabilities of Utah's Immigrant Children: Breaking the Cycle.....	215
	Grant Holyoak, Morgann Holyoak and Courtney G. Flint	
Chapter 21	Parents' and Teachers' Beliefs about School Readiness: Working toward Developing More Culturally Relevant Interventions.....	229
	Ellen Litkowski and Ann Cale Kruger	
Chapter 22	"I was Scared over There." Family Well-Being after Relocation from a Distressed Public Housing Development	241
	Kirstin Frescoln, Mai Thi Nguyen, William Rohe and Michael Webb	
Chapter 23	Learn, Eat, Grow: The Healthy Living Initiative	265
	Maya Bornstein	
Chapter 24	Should Parents Be Allowed to Refuse Vaccinations for Their Children?.....	277
	Dilip R. Patel and Kelly A. Brown	
Chapter 25	Food Security, Gender, and Occupational Seasonality in Urban Low-Income Households.....	285
	Shradhanvita Singh, Nehal A. Farooquee and Bikram K. Pattanaik	
Chapter 26	Traditional Health Care Practices of Women in Urban Slums: Focus on Maternal Health and Nutritional Status.....	295
	Shradhanvita Singh, Nehal A. Farooquee and Bikram K. Pattanaik	
Chapter 27	Chinese Beliefs about Adversity: Their Association with Treatment Fears among Young Psychotropic Substance Abusers in Hong Kong	307
	Yida Y. H. Chung and Daniel T. L. Shek	
Chapter 28	Validation of the Non-Conflict-Related Marital Quality Scale from the Perspective of Chinese Adolescent Children.....	315
	Hung-Kit Fok and Daniel T. L. Shek	

Chapter 29	Subjective Outcome Evaluation of a Training Program of Tin Ka Ping P.A.T.H.S. Project in China	327
	Daniel T. L. Shek, Tak Yan Lee and Jing Wu	
Chapter 30	Subjective Evaluation of a Training Program of the Tin Ka Ping P.A.T.H.S. Project in Mainland China	339
	Daniel T. L. Shek, Janet T. Y. Leung and Jing Wu	
Chapter 31	How do Teachers View and Experience a New General Education Program in Hong Kong? A Study Based on Descriptors and Open-Ended Questions.....	355
	Daniel T. L. Shek, Florence K. Y. Wu and Wen Yu Chai	
Chapter 32	Condom Use, Alcohol, and Alcohol-Related Personality Changes: A View from Russia	375
	Sergei V. Jargin	
Chapter 33	Factors Associated with Suicidal Ideation among In-School Adolescents, Uruguay	381
	Eric M. Njunju, Mwenya Kwangu, David Mulenga, Mazyanga L. Mazaba and Seter Siziya	
Chapter 34	Prevalence and Factors for Suicide Ideation among Adolescents Attending School in Ghana.....	391
	Mwenya Kwangu, David Mulenga, Mazyanga L. Mazaba, Eric M. Njunju and Seter Siziya	
Chapter 35	Prevalence and Correlates for Suicidal Ideation among Adolescents in School in Gaza Strip	401
	David Mulenga, Mazyanga L. Mazaba, Mwenya Kwangu, Eric M. Njunju and Seter Siziya	
Chapter 36	Prevalence and Correlates of Suicidal Ideation among School-Going Adolescents in Oman.....	409
	Mwenya Kwangu, Eric M. Njunju, David Mulenga, Mazyanga L. Mazaba and Seter Siziya	
Chapter 37	Factors Associated with Suicidal Ideation among Adolescents Attending School in Philippines	417
	Mwenya Kwangu, David Mulenga, Mazyanga L. Mazaba, Eric M. Njunju and Seter Siziya	
Chapter 38	Correlates of Suicidal Ideation among School-Going Adolescents in Bahamas	427
	Mwenya Kwangu, Seter Siziya, David Mulenga, Mazyanga L. Mazaba and Eric M. Njunju	

Chapter 39	Suicidal Ideation in Jamaica: Prevalence and Its Correlates among School-Going Adolescents in a Global School Health-Based Survey	437
	Seter Siziya, Eric M. Njunju, Mwenya Kwangu, David Mulenga and Mazyanga L. Mazaba	
Chapter 40	Suicidal Ideation Prevalence and Its Associated Factors among School-Going Adolescents in Pakistan.....	449
	Mwenya Kwangu, Eric M. Njunju, David Mulenga, Seter Siziya and Mazyanga L. Mazaba	
Chapter 41	Suicidal Ideation in Guyana: Prevalence and Its Associated Factors among Adolescents in a Global School Health-Based Survey	457
	Seter Siziya, Mazyanga L. Mazaba, Eric M. Njunju, Mwenya Kwangu and David Mulenga	
Chapter 42	Factors Associated with Suicidal Ideation among Adolescents Attending School in Samoa.....	467
	Seter Siziya, Aseel M. Almansour, David Mulenga, Mazyanga L. Mazaba, Eric M. Njunju and Mwenya Kwangu	
Chapter 43	Prevalence and Correlates for Suicidal Ideation among School-Going Adolescents in Iraq.....	477
	David Mulenga, Mwenya Kwangu, Eric M. Njunju, Mazyanga L. Mazaba and Seter Siziya	
Chapter 44	Correlates of Suicidal Ideation among In-School Adolescents in Trinidad and Tobago	485
	David Mulenga, Seter Siziya, Mazyanga L. Mazaba, Mwenya Kwangu and Eric M. Njunju	
Chapter 45	Factors Associated with Suicidal Ideation among Adolescents Attending School in Kuwait.....	495
	Mazyanga L. Mazaba, Seter Siziya, David Mulenga, Eric M. Njunju and Mwenya Kwangu	
Chapter 46	Suicidal Ideation in Fiji: Prevalence and Its Correlates among School-Going Adolescents in a Global School Health-Based Survey	505
	Mazyanga L. Mazaba, Eric M. Njunju, Mwenya Kwangu, David Mulenga and Seter Siziya	
Chapter 47	Prevalence and Correlates for Suicidal Ideation among Adolescents in School in West Bank	515
	Mazyanga L. Mazaba, David Mulenga, Mwenya Kwangu, Eric M. Njunju and Seter Siziya	

Chapter 48	Suicidal Ideation Prevalence and Its Associated Factors among In-School Adolescents in Morocco	527
	David Mulenga, Mwenya Kwangu, Eric M. Njunju, Seter Siziya and Mazyanga L. Mazaba	
Chapter 49	Suicidal Ideation in Vietnam: Prevalence and Its Associated Factors among Adolescents in a Global School Health-Based Survey	535
	Mazyanga L. Mazaba, Seter Siziya, Eric M. Njunju, Mwenya Kwangu and David Mulenga	
Chapter 50	Prevalence and Correlates for Suicidal Ideation among Adolescents in School in Bolivia	545
	Eric M. Njunju, David Mulenga, Mazyanga L. Mazaba, Mwenya Kwangu and Seter Siziya	
Chapter 51	Factors Associated with Suicidal Ideation among Adolescents Attending Junior High School in Suriname.....	555
	Eric M. Njunju, Mazyanga L. Mazaba, David Mulenga, Seter Siziya and Mwenya Kwangu	
Chapter 52	Correlates of Suicidal Ideation among In-School Adolescents in Myanmar	563
	Eric M. Njunju, Mwenya Kwangu, Seter Siziya, David Mulenga and Mazyanga L. Mazaba	
Chapter 53	Break the Cycle of Children's Environmental Health Disparities	573
	I. Leslie Rubin, Robert J. Geller, Claire D. Coles, Victoria Green, Abby Mutic, Nathan Mutic, Wayne Garfinkel, Benjamin A. Gitterman and Joav Merrick	
Chapter 54	Break the Cycle of Environmental Degradation	593
	I. Leslie Rubin	
Chapter 55	Risk Factors for Preeclampsia in a High-Risk Cohort of Women Served by a Nursing-Based Home Visiting Program	621
	Candace Tannis, Rachel Fletcher-Slater, Inessa Lopez, Alexandrah Gichingiri, Mario Cassara, Susanne Lachapelle and Elizabeth Garland	
Chapter 56	Evaluating Fish-Consumption in Pregnancy.....	633
	Ivorie Stanley and Susan Buchanan	
Chapter 57	Barriers and Promoters to Initiating and Sustaining Breastfeeding among African American Women	643
	Danielle Dimacali, Claribel Marmol, Jalisa Fortune, Jeannie Rodriguez and Helen Baker	

Chapter 58	Maternal Childhood Adversity and Early Parenting: Implications for Infant Neurodevelopment	661
	April L. Brown, Brooke G. McKenna, Madeleine F. Cohen, Anne L. Dunlop, Elizabeth J. Corwin and Patricia A. Brennan	
Chapter 59	Young Minds, Young Readers: Dialogic Reading with Adolescent Mothers and Their Children.....	673
	Diana L. Abarca, Jacqueline A. Towson, Barbara J. Ehren and Matthew S. Taylor	
Chapter 60	Changing Sleep Habits to Decrease Obesity	689
	Rebecca J. Graves, Leigh A. Minchew, Sonia Smith, Kimberly Zlomke, Kristina Caffey, Bridget Owens, Anna Thies, Megan Gibert and Sharon M. Fruh	
Chapter 61	The Relationship between Childhood Obesity and Neighborhood Food Environment Explored through the Context of Gentrification in New York City.....	703
	Brennan Rhodes-Bratton, Andrew Rundle, Gina S. Lovasi and Julie Herbstman	
Chapter 62	Relationship between Community Characteristics and School Engagement among United States Children, National Survey of Children's Health, 2011–2012	723
	Breyanna M. Mikel	
Chapter 63	Invisible Threats: Legal Methods to Address Asthma Triggers in Rental Homes	735
	Prathyusha Chenji	
Chapter 64	Children's Health and Safety Risks Posed by Irrigation Water in Northern Utah.....	749
	Kristen R. Koci and Courtney G. Flint	
Chapter 65	Environmental Justice for Vulnerable Florida Children in Hurricane Aftermath	763
	Manmit Singh, Dylan Avery and Valerie Mac	
Chapter 66	Social Media as a Tool for Breaking the Cycle of Children's Environmental Health Disparities	779
	Talia Bernhard, Faith Bygrave and Nsedu Obot Witherspoon	
Chapter 67	An Assessment of Anti-Vaccine: Reasons and Responses	789
	Satesh Bidaisee, Sadik Uddin, Emmanuel Keku and Joav Merrick	
Chapter 68	Depression in the Skies: An Occupational Health Issue among Pilots	795
	Satesh Bidaisee, Abishek Bala and Sadik Uddin	
Chapter 69	An Assessment of Mental Health among Refugee Communities	801
	Lefika Bathobakae, Maxwell Poirier, Titilope Saheed, Diem Quynh Nguyen and Satesh Bidaisee	

Chapter 70	Environmental Atrazine Exposure and Endocrine Health: Implications for Rural Communities in Midwestern United States	811
	Erica Ray and Kerry Mitchell	
Chapter 71	Communicable Diseases in the Windward Islands in the Caribbean: A Review of Health Status, 1990-2016	823
	Lindonne Glasgow, Shawn Charles, Kenisha James and Christine Richards	
Chapter 72	Measles Outbreak 2019: Re-Emergence in the United States	833
	James Jeongsub Lee, Prakash Ramdass and Angela Gomez	
Chapter 73	Vaccine Awareness for Cervical Cancer	845
	Sadik Uddin, Avi Bahadoor-Yetman and Emmanuel Keku	
Chapter 74	Efficacy of Combination Antimicrobial Therapy and Impact on Emerging Antimicrobial Resistance: A Twenty-Five Year Systematic Review	855
	Rhett McKnight, Vanessa Zabala and Satesh Bidaisee	
Chapter 75	Knowledge, Attitudes and Practices of Diabetic Patients at a Clinic in Grenada: Implications for HBA1c Levels	869
	Alisha R. Francis, Lindonne Glasgow, Lutz N. Amechi and Emmanuel Keku	
Chapter 76	Carnival Bacchanal Culture and the Silent HIV Risk among Female Caribbean Professionals	881
	Shivaughn Hem-Lee-Forsyth	
Chapter 77	Pet Ownership and Stress among University Students	895
	Maya Lantz, Maia P. Smith and Satesh Bidaisee	
Chapter 78	Quantification of Antimicrobial Prescribing Practices within Hampshire Hospitals NHS Foundation Trust	903
	Kathrine Lee-A-Ping, Jonathan Peters, Kordo Saeed, Matthew Dryden, Angela Gomez and Prakash Ramdass	
Chapter 79	Alcohol Consumption and Self-Reported Violence among Secondary School Aged Children (12-16 years) in 14 Caribbean Countries: A Cross Sectional Study	915
	Gerard St. Cyr	
Chapter 80	Managing Influenza Pandemics: Past and Future	933

	Stephanie Fletcher-Lartey, Lisa Indar, Tamu Davidson, Gabriel Gonzalez Escobar and Joy St. John	
Chapter 90	Rainwater Harvesting Water Quality Parameters Relevant to the Caribbean region: A Short Overview.....	1123
	Adrian Cashman and Clive Carpenter	
Chapter 91	Bacterial Vaginosis in Women of Reproductive Ages in Latin America and the Caribbean: A Literature Review	1133
	Attah Timothy Adejoh and Gerard St. Cyr	
Chapter 92	Recommendations for Developing Pesticide Exposure Prevention Programs in Caribbean countries.....	1145
	Lindonne Glasgow and Alicia C. McDonald	
Chapter 93	Breast Cancer in Grenada, West Indies: A Trend Analysis of Newly Diagnosed Breast Cancer Cases for the Period 2001-2010.....	1155
	Lindsey Moll, Moza Hamud, Victoria Watkins, Megan Ostlie, Zachary Kassirer, Vanessa Denny, Tolulope Oladimeji and Emmanuel Keku	

Chapter 94	Prostate Cancer in Grenada, West Indies: A Seven-Year Trend Analysis for the Period 2008-2014.....	1167
	Vandyke Jones, Colby Hansen, Bradley Wainoris, Caroline Bashour, Sulayman Khan, Charisse Douglas-Jones, Shelly Rodrigo and Emmanuel Keku	
Chapter 95	Epidemiologic Surveillance of Amputation in Grenada, 2010-2017	1179
	Shawn Charles and Lindonne Glasgow	
Chapter 96	Hazard and Risk Assessment of Rainwater Harvesting Systems in Carriacou, Grenada	1191
	Lindonne Glasgow and Jeremy Mendes	
Chapter 97	Knowledge, Attitudes and Practices Regarding Rainwater Harvesting in Carriacou, Grenada.....	1201
	Lindonne Glasgow and Jeremy Mendes	
Chapter 98	Assessment of Recreational Water Quality in the Southern Coastal Areas of Grenada	1211
	Sabrina Compton and Martin Forde	
Chapter 99	Metabolic Syndrome, Anxiety, and Depression in Aruban Adults	1225
	Sibel Dikmen, Marquesa Moore, Ezinma Schwiars and Prakash V. A. K. Ramdass	
Chapter 100	Prevalence of Metabolic Syndrome and Obesity among Adults in Aruba.....	1235
	Prakash V. A. K. Ramdass, Taisha Ford, Rita Alexander, Tanveer Sidhu, Chigozie F. Ogbonnia and Angela Gomez	
Chapter 101	Overweight and Obesity among Grenadian Adolescents	1245
	Richard Scribner, Roger Radix, Trevor Noel, Rebecca Andal, Naomi Andal, Christal Radix, Rhoda Frank, Jonell Benjamin, Jennifer James, Romero Benjamin, Claudia Leonardi and Melinda Sothern	
Chapter 102	Active Aging: WINDREF's Sports for Health Program among the Elderly in Grenada, West Indies.....	1253
	Satesh Bidaisee, Christina Wilson and Calum N. L. Macpherson	
Chapter 103	Differential Exposure to Social Determinants of Obesity among Rural and Urban Grenadian Adolescents	1263
	Roger Radix, Richard Scribner, Jerry Mitchell, Trevor Noel, Rebecca Andal, Naomi Andal, Christal Radix, Rhoda Frank, Jonell Benjamin, Jennifer James, Romero Benjamin Claudia Leonardi and Melinda Sothern	

Chapter 104	Analysis of Urine Samples for Antimicrobial Resistance Profiles in Grenada, 2015-2018.....	1273
	Michael J. Montalbano, Shawn Charles and Lindonne Glasgow	
Chapter 105	Trends in Morbidity and Mortality of Community-Acquired Pneumonia in Grenada during 2015-2019.....	1281
	Shawn Charles, Lindonne Glasgow, Joel Maruthanal and Prakash Ramdass	
Chapter 106	Health Impact and Multisectoral Response to a Major Flooding Event in Trinidad, October 2018.....	1289
	Laura-Lee G. Boodram, Corey Dillon, Sharis Garcia, Hannah H. Covert, Maureen Y. Lichtveld and Carl J. Hospedales	
Chapter 107	Service Leadership Education for University Students.....	1299
	Daniel T. L. Shek, Po Chung, Li Lin and Joav Merrick	
Chapter 108	Service Leadership Education at the City University of Hong Kong.....	1303
	Mark R. Hayllar, Linda Wong, Yanto Chandra, Maggie K. W. Lau, Eddie Yu, Joan Y. H. Leung and Timothy K. W. Ma	
Chapter 109	Service Leadership at Hong Kong Baptist University: A New Concept in General Education	1311
	A. Reza Hoshmand	
Chapter 110	Educating Students as the Leaders of Their Lives.....	1321
	Kin-Man Chan and Hugh Thomas	
Chapter 111	Grooming Service Leaders through Dynamic Teaching	1331
	Hugh Thomas	
Chapter 112	Prospective Service Leaders Enhancement Project.....	1341
	Loretta M. K. Leung, K. M. Chan and Maureen Y. L. Chan	
Chapter 113	Service Leadership Education at the Hong Kong Polytechnic University	1353
	Daniel T. L. Shek, Rachel C. F. Sun, Li Lin, Hildie Leung, Andrew M. H. Siu, Cecilia M. S. Ma, Lu Yu and Moon Y. M. Law	
Chapter 114	Service Leadership Community Blooming	1361
	Leo K. W. Hui, Ben Y. B. Chan and Ting-Chuen Pong	
Chapter 115	Challenges in the Development of an Experimental Course Series for Multi-Disciplinary Undergraduate Students.....	1369
	Kam Tim Woo, Sau Man Yuen, Chun Yin Leung and Lung Tak Ho	

Chapter 116	Key Practices of Leadership for Service in Hong Kong	1377
	Robin S. Snell, Maureen Y. L. Chan and Tracy X. P. Zou	
Chapter 117	Preparing Service Leaders from Lingnan University through Service-Learning Practicums in Social Enterprises and Non-Profit Organizations.....	1385
	Robin S. Snell, Maureen Y. L. Chan and Carol H. K. Ma	
Chapter 118	The Evaluation of Service Leadership Education for University Students in Hong Kong.....	1393
	Daniel T. L. Shek, Li Lin and Hildie Leung	
Chapter 119	Development and Validation of the Service Leadership Knowledge Scale in a Chinese Context	1403
	Daniel T. L. Shek, Li Lin, Hildie Leung, Lu Yu, Cecilia M. S. Ma and Xiang Li	
Chapter 120	Validation of the Service Leadership Knowledge Scale: Criterion-Related Validity	1419
	Daniel T. L. Shek and Li Lin	
Chapter 121	Content Validation of the Service Leadership Attitudes Scale	1431
	Daniel T. L. Shek, Li Lin, Hildie Leung, Lu Yu, Cecilia M. S. Ma and Xiang Li	
Chapter 122	Service Leadership Education in the University of Hong Kong	1445
	Jessie M. L. Chow and Samson Tse	
Chapter 123	Service Leadership Education in an Era of Service Economy.....	1455
	Daniel T. L. Shek, Xiaoqin Zhu and Joav Merrick	
Chapter 124	Impact of Service Leadership Education on University Students in Hong Kong.....	1459
	Wenyu Chai, Daniel T. L. Shek, Britta Lee and Meng Xie	
Chapter 125	Promotion of Well-Being and Leadership Qualities among University Students after Taking a Credit-Bearing Service Leadership Subject	1475
	Xiaoqin Zhu, Daniel T. L. Shek, Zhenli Zhu and Peixuan Zhao	
Chapter 126	Evaluation of an Intensive Service Leadership Program using the Subjective Outcome Evaluation Approach.....	1491
	Moon Y. M. Law, Daniel T. L. Shek and Jiaxi Zhang	
Chapter 127	Promotion of Service Leadership in University Students: Views of University Students	1509
	Daniel T. L. Shek, Robin K. H. Kwok and Siew Shen Low	

Chapter 128	Impact of a Leadership Program on the Holistic Development of University Students in Hong Kong	1525
	Moon Y. M. Law, Daniel T. L. Shek and Robin K. H. Kwok	
Chapter 129	The Effectiveness of a Service Leadership Subject in Hong Kong: A Qualitative Evaluation Study.....	1541
	Zi Yang, Daniel T. L. Shek and Jiaxi Zhang	
Chapter 130	A Qualitative Evaluation of a Service Leadership Subject in a Higher Educational Institution in Hong Kong	1559
	Zi Yang, Daniel T. L. Shek and Jiaxi Zhang	
Chapter 131	Development and Evaluation of a Service Leadership Subject in a Blended Learning Mode.....	1575
	Xiaoqin Zhu, Daniel T. L. Shek, Diya Dou and Wenyu Chai	
Chapter 132	Development and Validation of Assessment Tools on Service Leadership Knowledge, Attitude and Behavior.....	1593
	Daniel T. L. Shek, Xiaoqin Zhu and Joav Merrick	
Chapter 133	Leadership Assessment Tools in Different Chinese Contexts	1599
	Li Lin and Daniel T. L. Shek	
Chapter 134	Conceptual Background and the Development of Service Leadership Knowledge Scale	1611
	Daniel T. L. Shek, Xiaoqin Zhu and Alex Y. F. Zhu	
Chapter 135	Development of the Attitude to Service Leadership Scale in Hong Kong.....	1623
	Cecilia M. S. Ma, Daniel T. L. Shek and Yanto Chandra	
Chapter 136	Development of Service Leadership Behavior Scale: Background and Conceptual Model.....	1637
	Daniel T. L. Shek, Xiaoqin Zhu and Kin-Man Chan	
Chapter 137	Psychometric Properties of the Service Leadership Behavior Scale: Preliminary Findings	1649
	Daniel T. L. Shek, Lawrence K. Ma and Hildie Leung	
Chapter 138	Content Validation of a Service Leadership Behavior Scale in Hong Kong	1669
	Daniel T. L. Shek, Jing Wu, Li Lin and Xiang Li	
Chapter 139	Validation of the Service Leadership Knowledge Scale: Factorial and Convergent Validity	1683
	Daniel T. L. Shek, Lawrence K. Ma and Loretta M. K. Leung	
Chapter 140	Validation of the Service Leadership Attitude Scale in Hong Kong.....	1699
	Daniel T. L. Shek, Alex Y. F. Zhu, Lawrence K. Ma and Li Lin	

Chapter 141	Convergent and Factorial Validation of the Service Leadership Behavior Scale.....	1713
	Daniel T. L. Shek, Lawrence K. Ma, Cecilia M. S. Ma and A. Reza Hoshmand	
Chapter 142	The Service Leadership Knowledge Scale: Norms and Psychological Correlates.....	1731
	Daniel T. L. Shek, Xiaoqin Zhu and Samson Tse	
Chapter 143	The Service Leadership Attitude Scale: Normative Data and Personal Correlates in Chinese University Students.....	1747
	Daniel T. L. Shek, Jing Wu and Ben Y. B. Chan	
Chapter 144	The Service Leadership Behavior Scale: Norms and Personal Correlates.....	1763
	Daniel T. L. Shek, Diya Dou and Robin S. Snell	
Chapter 145	A User Manual for the Service Leadership Knowledge Scale	1779
	Daniel T. L. Shek, Lawrence K. Ma, Siew Shen Low, Xiaoqin Zhu and Diya Dou	
Chapter 146	A User Manual for Service Leadership Attitude Scale.....	1795
	Daniel T. L. Shek, and Xiaoqin Zhu	
Chapter 147	A User Manual for the Service Leadership Behavior Scale	1819
	Daniel T. L. Shek, Xiaoqin Zhu and Diya Dou	
Chapter 148	Origin, Development and Assertions of Service Leadership Theory	1839
	Daniel T. L. Shek and Zi Yang	
Chapter 149	Humanistic Leadership in Service Economy	1855
	Xiaoqin Zhu, Daniel T. L. Shek and Daniel C. H. Ng	
Chapter 150	Moral Character in the Service Leadership Theory.....	1869
	Diya Dou, Daniel T. L. Shek and Zhenli Zhu	
Chapter 151	The Dark Side of Leadership in the Service Leadership Theory	1885
	Diya Dou and Daniel T.L. Shek	
Chapter 152	Caring Leadership in Service Economy.....	1897
	Xiaoqin Zhu, Daniel T. L. Shek and Zhenli Zhu	
Chapter 153	The Role of Trust in the Service Economy	1911
	Wenyu Chai and Daniel T. L. Shek	
Chapter 154	Self-Leadership in the Service Leadership Theory.....	1925
	Wenyu Chai, Daniel T. L. Shek and Diya Dou	
Chapter 155	The Fung Service Leadership Initiative in Hong Kong	1939
	Daniel T. L. Shek and Zi Yang	

Chapter 156	Can We Nurture University Students to Become the Leaders of Tomorrow?	1955
	Daniel T. L. Shek, Cecilia M. S. Ma and Joav Merrick	
Chapter 157	Emotional Competence.....	1959
	Daniel T. L. Shek and Cecilia M. S. Ma	
Chapter 158	Cognitive Competence.....	1971
	Daniel T. L. Shek and Lu Yu	
Chapter 159	Development of a Clear and Positive Identity	1985
	Daniel T. L. Shek and Florence K. Y. Wu	
Chapter 160	Resilience, Leadership and Intrapersonal Development.....	1995
	Daniel T. L. Shek and Hildie Leung	
Chapter 161	Developing Self-Leadership and Responsibility.....	2007
	Daniel T. L. Shek and Hildie Leung	
Chapter 162	Developing Social Competence	2021
	Daniel T. L. Shek and Janet T. Y. Leung	
Chapter 163	Spirituality	2035
	Daniel T. L. Shek and Wynants W. L. Ho	
Chapter 164	Moral Competence.....	2045
	Daniel T. L. Shek and Wynants W. L. Ho	
Chapter 165	Reflective Teaching and Holistic Personal Development	2055
	Cecilia M. S. Ma	
Chapter 166	Reflection of a Teacher	2067
	Lu Yu	
Chapter 167	Reflections about “Knowing Thyself”	2079
	Florence K. Y. Wu	
Chapter 168	Levels of Reflection	2091
	Hildie Leung	
Chapter 169	Riding on a Roller Coaster.....	2107
	Janet T. Y. Leung	
Chapter 170	Evaluation of a Service Leadership Project.....	2121
	Daniel T. L. Shek, Moon Y. M. Law and Jianqiang Liang	
Chapter 171	Qualitative Evaluation of Leadership	2131
	Daniel T. L. Shek, Hung-Kit Fok, Charles T. L. Leung, Pecky P. K. Li and Moon Y. M. Law	
Chapter 172	Focus Group Evaluation.....	2147
	Daniel T. L. Shek, Florence K. Y. Wu, Charles T. L. Leung, Hung-Kit Fok, Pecky P. K. Li and Moon Y. M. Law	

Chapter 173	Evaluation of a Leadership and Intrapersonal Development Program.....	2161
	Cecilia M. S. Ma, Daniel T. L. Shek, Pecky P. K. Li, Betty P. W. Mok and Edvina Y. K. Leung	
Chapter 174	A New 4-Year Undergraduate Program in Hong Kong	2173
	Daniel T. L. Shek, Lu Yu and Joav Merrick	
Chapter 175	Leadership Qualities as a Foundation of Service Learning	2177
	Daniel T. L. Shek	
Chapter 176	Service-Learning as a Mandatory Credit-Bearing Subject.....	2191
	Stephen C. F. Chan, Grace Ngai and Daniel T. L. Shek	
Chapter 177	University Social Responsibility and Promotion of the Quality of Life	2209
	Daniel T. L. Shek	
Chapter 178	What Should be the Desired Attributes of Youth Leaders?.....	2223
	Daniel T. L. Shek and Angelina Yuen	
Chapter 179	General Education at The Hong Kong Polytechnic University	2249
	Daniel T. L. Shek, Lu Yu and Kevin H. W. Chan	
Chapter 180	The Achievement of Desired University Graduate Attributes.....	2265
	Daniel T. L. Shek, Lu Yu, Wen Yu Chai, Florence K. Y. Wu and Wynants W. L. Ho	
Chapter 181	The Perceptions of Teachers of the New General Education Curriculum in Hong Kong.....	2279
	Daniel T. L. Shek, Catherine W. Y. Chai and Florence K. Y. Wu	
Chapter 182	The Well-Being of University Students in Hong Kong.....	2293
	Florence K. Y. Wu, Daniel T. L. Shek and Julie X. Q. Zhu	
Chapter 183	The Development of Undergraduate University Students.....	2305
	Daniel T. L. Shek, Wen Yu Chai, Huijing Lu, Lu Yu, Kevin H. W. Chan, Wynants W. L. Ho, Cecilia M. S. Ma, Florence K. Y. Wu, Hildie Leung, Li Lin and Moon Law	
Chapter 184	General University Requirements and Holistic Development in University Students	2323
	Daniel T. L. Shek and Lu Yu	
Chapter 185	The Impact of Three-Year and Four-Year Undergraduate Programs on University Students.....	2335
	Daniel T. L. Shek and Lu Yu	
Chapter 186	The View of the Teacher in a New General Education Program in Hong Kong.....	2347
	Daniel T. L. Shek, Lu Yu and Florence K. Y. Wu	

Chapter 187	A Focus Group Evaluation of Teachers' Views Concerning a New General Education Program	2361
	Daniel T. L. Shek and Lu Yu	
Chapter 188	What Did the Students Say?	2375
	Daniel T. L. Shek and Lu Yu	
Chapter 189	Student Feedback on a Pioneer Subject on Leadership and Intrapersonal Development	2389
	Daniel T. L. Shek and Lu Yu	
Chapter 190	Qualitative Evaluation of the General University Requirements	2399
	Daniel T. L. Shek, Lu Yu and Florence K. Y. Wu	
Chapter 191	An Evaluation Study on a University General Education Subject in Hong Kong.....	2415
	Daniel T. L. Shek and Lu Yu	
Chapter 192	History and Background of Vasculitis	2427
	Eric L. Matteson	
Chapter 193	Overview of Primary and Secondary Vasculitides	2441
	David S. Younger	
Chapter 194	Epidemiology of Primary Systemic Vasculitis.....	2489
	Richard A. Watts and Joanna Robson	
Chapter 195	Health Related Quality of Life and Its Measurement in the Vasculitides	2507
	Joanna Robson and Richard A. Watts	
Chapter 196	Neutrophilic Cell Pathobiology in the Vasculitides.....	2519
	Akihiro Ishizu	
Chapter 197	Complement Factors in ANCA-Associated Vasculitis.....	2527
	Chen Wang and Min Chen	
Chapter 198	Experimental Autoimmune Vasculitis: Insights into Human Vasculitis Using Animal Models	2551
	Alan D. Salama and Mark A. Little	
Chapter 199	Genetic Aspects of Vasculitis	2561
	F. David Carmona, Ana Márquez, Javier Martín and Miguel A. González-Gay	
Chapter 200	Nomenclature and Pathologic Features of Vasculitides	2595
	J. Charles Jennette, Ronald J. Falk and Adil. H. M. Gasim	
Chapter 201	Classification of Pediatric Vasculitides	2617
	Seza Ozen	
Chapter 202	Detection Techniques and Clinical Relevance of ANCA Testing.....	2627
	Elena Csernok, Juliane Mahrhold and Bernhard Hellmich	

Chapter 203	Classification and Pathogenicity of ANCA-Associated Vasculitis.....	2635
	Alexander Tracy, Constantina Yiannakis, Lorna Ward and Matthew David Morgan	
Chapter 204	Cryoglobulinemic Vasculitis	2661
	Clodoveo Ferri, Dilia Giuggiol, Marco Sebastiani and Michele Colac	
Chapter 205	Aortitis and Periaortitis.....	2675
	Eugenia Accorsi Buttini, Chiara Marvisi and Augusto Vaglio	
Chapter 206	Systemic Vasculitis and the Lung.....	2703
	Christian Pagnoux, Noura Mustapha and Gerard Cox	
Chapter 207	Systemic Vasculitis and the Kidney: ANCA-Associated Vasculitis and Glomerulonephritis.....	2725
	Koyal Jain, Manish Saha and Ronald J. Falk	
Chapter 208	Anti-Glomerular Basement Membrane Disease	2747
	Stephen P. McAdoo and Charles D. Pusey	
Chapter 209	Systemic Vasculitis of the Gastrointestinal Tract	2773
	Daniel Geh, Dimitrios Chanouzas and Matthew David Morgan	
Chapter 210	Rheumatoid Arthritis Vasculitis.....	2801
	Elana J. Bernstein and Robert F. Spiera	
Chapter 211	Dermatologic Aspects of Systemic Vasculitis	2817
	Rami N. Al-Rohi, Ruben Peredo-Wende and J. Andrew Carlson	
Chapter 212	The Clinical Approach to Patients with Vasculitis	2855
	David S. Younger	
Chapter 213	Polyarteritis Nodosa.....	2871
	Loïc Raffray and Loïc Guillevin	
Chapter 214	Giant Cell Arteritis	2901
	David S. Younger	
Chapter 215	Ophthalmologic and Neuro-Ophthalmologic Aspects of Vasculitides	2925
	David S. Younger	
Chapter 216	The Blood-Brain Barrier	2957
	David S. Younger	
Chapter 217	Neuroimaging of CNS Vasculitis	2973
	Eytan Raz, Adam Davis and David S. Younger	
Chapter 218	Adult Primary Angiitis of the Central Nervous System and Related Syndromes.....	2991
	Rula A. Hajj-Ali and Leonard H. Calabrese	

Chapter 219	Primary CNS Vasculitis: Pathophysiological Diversity.....	3003
	Nicolò Pipitone, Gene G. Hunder and Carlo Salvarani	
Chapter 220	Stroke Due to Vasculitis in Adults.....	3013
	David S. Younger	
Chapter 221	Central Nervous System Vasculitis Due to Infection	3031
	David S. Younger and Patricia K. Coyle	
Chapter 222	Peripheral Nerve Vasculitis: Classification and Disease Associations	3057
	Kelly G. Gwathmey, Jennifer A. Tracy and P. James B. Dyck	
Chapter 223	Central Nervous System Vasculitis Due to Drug Abuse.....	3083
	David S. Younger	
Chapter 224	Autoimmune Encephalitides	3109
	David S. Younger	
Chapter 225	Overview of the Treatment of Primary Systemic Vasculitis	3137
	Antoine Sreih and Peter A. Merkel	
Chapter 226	How Knowledgeable Are Young Adults about Alzheimer's Disease?	3157
	Ronald Chow, Michael Borean, Drew Hollenberg and Joav Merrick	
Chapter 227	Awareness of Alzheimer's Disease: About the Survey and Survey Instrument.....	3161
	Ronald Chow, Michael Borean and Drew Hollenberg	
Chapter 228	Awareness of Alzheimer's Disease among Young Adults in London, Canada	3167
	Ronald Chow, Alexandra Ferrara, Michael Borean, Drew Hollenberg, Michael Lam, Tharani Anpalagan, Jaclyn Viehweger and Anna Rzepka	
Chapter 229	Awareness of Alzheimer's Disease among Young Adults in Kingston, Canada	3175
	Ronald Chow, Michael Borean, Drew Hollenberg, Logan Midroni, Cooper Midroni, Yeonju Kim, Tharani Anpalagan, Jaclyn Viehweger and Anna Rzepka	
Chapter 230	Awareness of Alzheimer's Disease among Young Adults in Toronto, Canada.....	3183
	Michael Borean, Anna Rzepka, Victoria Trasente, Drew Hollenberg, Cynthia Ho, Wesley Ng, Matthew Wong, Tharani Anpalagan, Jaclyn Viehweger and Ronald Chow	

Chapter 231	Awareness of Alzheimer's Disease among Young Adults in Ottawa, Canada	3193
	Jaclyn Viehweger, Michael Borean, Drew Hollenberg, Tharani Anpalagan, Anna Rzepka, Victoria Trasente and Ronald Chow	
Chapter 232	Awareness of Alzheimer's Disease among Young Adults in Hamilton, Canada.....	3201
	Tharani Anpalagan, Michael Borean, Drew Hollenberg, Ineka Panigrahi, Jaclyn Viehweger, Anna Rzepka, Victoria Trasente and Ronald Chow	
Chapter 233	Awareness of Alzheimer's Disease among Young Adults in Waterloo, Canada	3209
	Drew Hollenberg, Michael Borean, Jerry Liu, Tharani Anpalagan, Jaclyn Viehweger, Victoria Trasente, Anna Rzepka and Ronald Chow	
Chapter 234	Awareness of Alzheimer's Disease among Young Adults in Saskatoon, Canada	3217
	Jaclyn Viehweger, Drew Hollenberg, Michael Borean, Rahul Parekh, Vladimir Grujic, Aadyn Oleksyn, Tharani Anpalagan, Anna Rzepka, Victoria Trasente and Ronald Chow	
Chapter 235	Awareness of Alzheimer's Disease among Young Adults in Montreal, Canada	3227
	Anna Rzepka, Drew Hollenberg, Michael Borean, Tharani Anpalagan, Kevin Song, Jacie Liu, Tyler Young, Jaclyn Viehweger and Ronald Chow	
Chapter 236	Awareness of Alzheimer's Disease among Young Adults in North Carolina, United States	3235
	Ronald Chow, Jaclyn Viehweger, Drew Hollenberg, Michael Borean, Tharani Anpalagan, Victoria Trasente and Anna Rzepka	
Chapter 237	Awareness of Alzheimer's Disease among Young Adults in New York State, United States	3243
	Michael Borean, Drew Hollenberg, Neal Ganguli, Ray Kang, William Bai, Tharani Anpalagan, Jaclyn Viehweger, Victoria Trasente, Anna Rzepka and Ronald Chow	
Chapter 238	Awareness of Alzheimer's Disease among Young Adults in Dublin, Ireland.....	3253
	Ronald Chow, Drew Hollenberg, Michael Borean, Samuel Goh, Tharani Anpalagan, Jaclyn Viehweger, Horace Looi, Stephanie Ho, Victoria Trasente and Anna Rzepka	

Chapter 239	Awareness of Alzheimer's Disease among Young Adults in Asia	3261
	Jaclyn Viehweger, Drew Hollenberg, Michael Borean, Samuel Fung, Tharani Anpalagan, Victoria Trasente, Anna Rzepka and Ronald Chow	
Chapter 240	Young Adults and Awareness of Alzheimer's Disease: A Meta-Analysis	3269
	Ronald Chow, Michael Borean and Drew Hollenberg	
Chapter 241	Young Adults and Awareness of Alzheimer's Disease by Age, Sex and Familial Ties: A Meta-Analysis	3281
	Ronald Chow, Michael Borean and Drew Hollenberg	
Chapter 242	Associations with Obesity in Sub-Saharan Africa	3307
	Yackoob K. Seedat	
Chapter 243	Metabolic Syndrome in the Philippines and Asia: Concepts and Concerns	3315
	Gabriel V. Jasul, Jr., Rosa Allyn G. Sy and Rodolfo F. Florentino	
Chapter 244	Body Mass Index, Percent Body Fat and Fat Mass Index as Screening Tools for General Obesity among Adult Females of Amritsar (Punjab)	3331
	Ramanpreet Randhawa and Sharda Sidhu	
Chapter 245	The Association of Central Adiposity with Metabolic Syndrome among the Bhutias of Sikkim, India.....	3353
	Sovanjan Sarkar and Barun Mukhopadhyay	
Chapter 246	Bisexual Differences in the Association of Adiposity Measures with the Risk of Hypertension among the Tribes of Gujarat, India	3365
	Gautam K. Kshatriya	
Chapter 247	Obesity as an Important Predictor of Hypertension among Rajshahi University Students in Bangladesh: A Cross-Sectional Study	3385
	Md. Golam Hossain, Sadekur Rahman, Suhaili Mohd, Saw Aik, Rashidul Alam Mahumud, Premananda Bharati and Pete E. Lestrel	
Chapter 248	Increasing Incidence of Macrosomia: The Impact of Maternal Somatic and Behavioral Parameters on Newborn Weight Status.....	3401
	Sylvia Kirchengast	
Chapter 249	Metabolic Disorder and Type-2 Diabetes Associations with Anthropometric Measures among Adult Asian Indians	3417
	Sampriti Debnath, Nitish Mondal and Jaydip Sen	

Chapter 250	C-Reactive Protein and Family History: A Future Threat towards Diabetes and Syndrome X.....	3439
	Riddhi Goswami, Mithun Das and Indrani Lodh	
Chapter 251	Sensitivity and Specificity of Body Mass Index to Assess Excess Adiposity.....	3449
	Jyoti Ratan Ghosh	
Chapter 252	Framing Obesity and Undernutrition as Problems for Governments.....	3457
	Stanley Uljaszek	
Chapter 253	Modernization and Obesity: A Pandemic Issue	3471
	Soibam Jibonkumar Singh and Thoudam Bedita Devi	
Chapter 254	Obesity and Syndrome X.....	3483
	Anup Adhikari	
Chapter 255	Syndrome X: Some Common Determinants Worldwide.....	3487
	Mithun Das and Kaushik Bose	
Chapter 256	Break the Cycle of Children's Environmental Health Disparities.....	3499
	I. Leslie Rubin, Robert J. Geller, Kurt Martinuzzi, Abby Mutic, Nathan Mutic, Benjamin A. Gitterman, Wayne Garfinkel, Claire D. Coles and Joav Merrick	
Chapter 257	Resilience: A Commentary on Breaking the Cycle.....	3515
	I. Leslie Rubin	
Chapter 258	Maternal Drug Use and the Severity of Neonatal Abstinence Syndrome.....	3533
	Pratibha Agarwal, Beth Bailey, Jesi Hall, Michael Devoe and David Wood	
Chapter 259	Mothers in Prison.....	3545
	Tatenda Mangurenje and Melvin J. Konner	
Chapter 260	Housing Instability and Child Growth and Development.....	3561
	Abigail L. Gaylord, Whitney J. Cowell, Lori A. Hoepner, Frederica P. Perera, Virginia A. Rauh and Julie B. Herbstman	
Chapter 261	DDT Exposure, Socio-Economic Status and Neurodevelopmental Outcomes in Children	3573
	Nosiku S. Munyinda, Sandra Shanungu, Given Moonga and Charles C. Michelo	
Chapter 262	Racial Disparities in Access to Municipal Water Supplies in the American South.....	3587
	Frank Stillo and Jacqueline MacDonald Gibson	

Chapter 263	A Silver Lining for Neonatal Intensive Care (NICU) Graduates: Coordinated Services from 0-6 Years	3607
	Lea Redd, Ren Belcher, Brianne Dotts and Bree Andrews	
Chapter 264	Exploring the Role of Social Support in Understanding Barriers to Breastfeeding Practices for Adolescent Mothers.....	3617
	Colleen Clark and Kimberly Price	
Chapter 265	A Community-Based Program to Decrease the Risk of Childhood Obesity	3629
	Hope Bentley, Jannett Lewis-Clark, Alfonso Robinson Jr., Brittany McCullough, Vanessa Harris, Kayla Bryan, Precious Harris, Teralesha Baity and Chante' Warner	
Chapter 266	A Lead Education Program with the Boys and Girls Club of Metro Atlanta	3639
	Amrita G. Mahtani, Catherine G. Evans, Samuel J. W. Peters, Patrick O. Fueta and William M. Caudle	
Chapter 267	Report to Congress on Traumatic Brain Injury in the United States: Understanding the Public Health Problem among Current and Former Military Personnel	3665
	CDC, NIH, DOD, and VA Leadership Panel	
Chapter 268	The Spatial Analysis of Air Pollution Parameters (PM₁₀, SO₂ and NO₂): A Case Study of the Marmara Region (2014-2017)	3757
	Ozer Akyurek	
Chapter 269	Obesity, Obesity Surgery and Nursing Care	3769
	Züleyha Şimşek Yaban	
Chapter 270	Effect of Global Climate Change on Occupational Health: Heat Stress	3781
	Serap Arsal Yildirim	
Chapter 271	Physical Activity in Women	3791
	Asuman Saltan	
Chapter 272	The Enhanced Recovery after Surgery Protocol and the Role of Surgical Nurses.....	3801
	Selda Mert Boğa	
Chapter 273	Current Approaches to Prevent Diabetic Foot Ulcers.....	3813
	Ayfer Peker	
Chapter 274	A Review of Studies on the Application of Coumarin and Its Derivatives in Plants.....	3823
	Burcu Yuksel	
Chapter 275	Awareness of Brucellosis: A Worldwide Zoonosis	3835
	Mustafa Sencer Karagul	

Chapter 276	Mutagenic Potential of the Insecticide Arrivo 25 EC on Mitosis and Meiosis of <i>Hyacinthus orientalis</i>.....	3851
	Ozlem Aksoy, Aylın Horozal and Burcu Yuksel	
Chapter 277	Aluminum-Induced Toxicity and Programmed Cell Death in Plants	3863
	Filiz Vardar, Fatma Yanık, Aslıhan Çetinbaş-Genç and Gamze Kurtuluş	
Chapter 278	Comparative Analysis of Different Regions of Rat Brain Tissue by FT-IR Spectroscopy.....	3881
	Sevgi Türker Kaya, Dilan Yıldırım, Didem Şentürk, Kübra Dağcı and Gül İlbaş	
Chapter 279	Single Cell Gel Electrophoresis for Determination of Plant Responses to Genotoxic Stress.....	3895
	Yıldız Aydın, Ahu Altınkut Uncuoğlu and Filiz Vardar	
Chapter 280	Evaluation of the Sensitivity of the Nurses Working in Surgical Services of a Public Hospital to Patient Rights	3909
	Selda Mert Boga and Aylin Aydın Sayılan	
Chapter 281	Control and Eradication of Animal Brucellosis	3921
	Mustafa Sencer Karagül	
Chapter 282	Small Ruminant Morbillivirus.....	3933
	Ahmet Sait	
Chapter 283	Ultra-High Molecular Weight Polyethylene for Medical Applications	3941
	Merve Dandan Doganci and Erdinc Doganci	
Chapter 284	Nursing Care for the Symptoms of Cancer Treatment	3957
	Aylin Aydın Sayılan	
Chapter 285	Mortality and Life Expectancy in Post-Communist Countries: What Are the Lessons for Other Countries?	3971
	Vladimir Popov	
Chapter 286	A Theory of Why Potentially Favourable Political and Economic Changes May Lead to Mortality Crises	3987
	Giovanni Andrea Cornia	
Chapter 287	Mortality Crises in High-Income Countries: Evidence from the United States, the United Kingdom, Italy, and Greece	4007
	Roberto De Vogli	
Chapter 288	The Mortality Crisis of the Former Soviet Bloc Countries, 1989-2014.....	4043
	Giovanni Andrea Cornia	

Chapter 289	Mortality Crisis in Russia Revisited: Evidence from a Cross-Regional Comparison	4073
	Vladimir Popov	
Chapter 290	The Path of Economic Development and Health Status: Evidence from China	4087
	Yue Teng and Luca Bortolotti	
Chapter 291	Policy Reform from the Early 1990s and Changes in Health Status in India: 1991–2016	4115
	C. P. Chandrasekhar and Jayati Ghosh	
Chapter 292	Lactic Acid Bacteria against Spoilage and Pathogenic Microorganisms in Food.....	4139
	Marcela P. Castro, Carmen A. Campos, María E. Cayré, Laura I. Schelegueda, Nadia Galante and Sofía B. Delcarlo	
Chapter 293	Thermotolerant Probiotic Lactic Acid Bacteria in Cooked Meat Products.....	4169
	M. L. Pérez-Chabela	
Chapter 294	Microencapsulated Lactic Acid Bacteria in Meat Products.....	4183
	Daneysa L. Kalschne, Rosana A. Silva-Buzanello, Marinês P. Corso, Eliane Colla and Cristiane Canan	
Chapter 295	Lactic Acid Bacteria Responses to Osmotic Challenges	4201
	Maria K. Syrokou, Spiros Paramithiotis and Eleftherios H. Drosinos	
Chapter 296	Lactic Acid Bacteria as Source of Biosurfactants	4213
	Carmen A. Campos, Virginia M. Lara and María F. Gliemmo	
Chapter 297	Antimicrobial Bacteriocins and Peptidoglycan Hydrolases: Beneficial Metabolites Produced by Lactic Acid Bacteria	4233
	Adriana López-Arvizu, Israel García-Cano, María de Lourdes Pérez-Chabela and Edith Ponce-Alquicira	
Chapter 298	Bioactive Peptides Generated by Lactic Acid Bacteria	4265
	Marcela P. Castro, Noelia Z. Palavecino Prpich and María E. Cayré	
Chapter 299	Antimicrobial Products: An Important Feature of Lab and Their Applications	4277
	Sujitra Techo and Somboon Tanasupawat	
Chapter 300	Diversity and Production of γ-Aminobutyric Acid by Lactic Acid Bacteria	4303
	Sukanya Phuengjayaem and Somboon Tanasupawat	

Chapter 301	<i>Lactococcus lactis</i> as a DNA Vaccine Delivery System.....	4323
	Vanessa Bastos Pereira, Tatiane Melo Preisser, Camila Prósperi De Castro, Bianca Mendes Souza, Meritxell Zurita Turk, Vanessa Pecini da Cunha and Anderson Miyoshi	
Chapter 302	Bile Salt Hydrolase Activity of Lactic Acid Bacteria: A Potential for Health.....	4339
	Engkarat Kingkaew and Somboon Tanasupawat	
Chapter 303	Exopolysaccharides from <i>Lactobacillus</i>: Biosynthesis, Characterization, Functional Aspects and Applications in Food Industry.....	4353
	Elisa C. Ale, Jorge A. Reinheimer and Ana G. Binetti	
Chapter 304	Spore-Forming Lactic Acid Bacteria and Their Abilities for Utilization	4387
	Sitanan Thitiprasert, Nuttha Thongchul and Somboon Tanasupawat	
Chapter 305	Public Health Significance of Fringillidae: Viral, Bacterial, Mycotic, Parasitic and Allergenic Approaches	4409
	Hadi Tavakkoli	
Chapter 306	The Role of <i>Sphingomonas paucimobilis</i> in Intergeneric Co-Aggregation and Mixed Biofilm Formation with Water Borne Pathogenic Bacteria in the Distributed Drinking Water System: Implications of Public Health Risk	4463
	Parul Gulati and Moushumi Ghosh	
Chapter 307	Parenting and Family Life in Hong Kong: Traditional Perspective, Contemporary Research and Intervention	4483
	Daniel T. L. Shek, Moon Y. M. Law and Joav Merrick	
Chapter 308	Parental Expectations amongst Chinese Parents in Hong Kong: Profiles and Demographic Correlates.....	4487
	Daniel T. L. Shek, Ching Man Lam and Xiaoqin Zhu	
Chapter 309	Gendered Expectation towards Sons and Daughters in Chinese Parents in Hong Kong.....	4501
	Daniel T. L. Shek, Wai Man Kwong, Xiaoqin Zhu and Zi Yang	
Chapter 310	Division of Labor in Parenting amongst Chinese Parents in Hong Kong	4515
	Daniel T. L. Shek, Ching Man Lam and Zi Yang	
Chapter 311	Parental Beliefs about Parental Roles and Responsibilities in Chinese Parents: Pioneer Findings	4529
	Daniel T. L. Shek, Siu-Ming To and Diya Dou	

Chapter 312	Parenting in Contemporary Hong Kong: Observations and Reflections.....	4545
	Daniel T. L. Shek and Moon Y. M. Law	
Chapter 313	“Di Zi Gui” (Standards for Being a Good Student and Child): Implications for Children and Youth Development and Parenting.....	4559
	Daniel T. L. Shek and Moon Y. M. Law	
Chapter 314	Promotion of Family Life Quality amongst Adolescents: The Project P.A.T.H.S. in Hong Kong	4579
	Daniel T. L. Shek and Moon Y. M. Law	
Chapter 315	Advances in Chinese Children, Adolescent and Family Research.....	4605
	Moon Y. M. Law, Daniel T. L. Shek, Ariel Tenenbaum and Joav Merrick	
Chapter 316	Reliability and Validity of the Chinese Version of the Psycho-Educational Profile (Third Edition) for Children with Developmental Problems	4609
	Daniel T. L. Shek and Lu Yu	
Chapter 317	The Impacts of a UNICEF Health Promotion Project on Primary Health Care in Western China: A Comprehensive Evaluation at Provincial Level	4627
	Yuxue Bi, Dejian Lai and Hong Yan	
Chapter 318	Materialism in Chinese Adolescents in Hong Kong: Profiles and Socio-Demographic Correlates.....	4641
	Daniel T. L. Shek, Li Lin, Andrew M. H. Siu and Britta M. Lee	
Chapter 319	Materialism and Egocentrism in Chinese Adolescents in Hong Kong: Perceptions of Teachers	4655
	Daniel T. L. Shek, Cecilia Ma, Andrew M. H. Siu and Britta M. Lee	
Chapter 320	Family Mealtime Environment and Child Behavior Outcomes in Chinese Preschool Children.....	4669
	Cynthia Leung, Sandra Tsang, Sing Kai Lo and Ruth Chan	
Chapter 321	Families in Transition in Hong Kong: Implications to Family Research and Practice.....	4681
	Janet T. Y. Leung and Daniel T. L. Shek	
Chapter 322	Subjective Outcome Evaluation of the Tin Ka Ping P.A.T.H.S. Project in China: View of the Students.....	4699
	Daniel T. L. Shek, Tak Yan Lee, Xiaoqin Zhu and Lawrence K. Ma	

Chapter 323	Evaluation of the Project P.A.T.H.S. in Mainland China: Views of the Program Implementers in Senior High Schools	4711
	Daniel T. L. Shek, Florence K. Y. Wu, Rachel C. F. Sun and Mengtong Chen	
Chapter 324	Evaluation of the Training Program of a Positive Youth Development Program: Tin Ka Ping P.A.T.H.S. Project in China	4723
	Daniel T. L. Shek, Janet T. Y. Leung, Rachel C. F. Sun, Mengtong Chen and Chi Kin Chung	
Chapter 325	Tin Ka Ping P.A.T.H.S. Project in Mainland China: Preliminary Evaluation Findings	4739
	Daniel T. L. Shek, Tak-Yan Lee, Rachel C. F. Sun, Florence K. Y. Wu and Janet T. Y. Leung	
Chapter 326	Evaluation Findings of Tin Ka Ping P.A.T.H.S. Project Implemented in Junior Secondary Schools: Implementers' Views	4749
	Daniel T. L. Shek, Xiaoqin Zhu and Janet T. Y. Leung	
Chapter 327	Subjective Outcome Evaluation of the Tin Ka Ping P.A.T.H.S. Project: Views of Senior Secondary School Students.....	4761
	Daniel T. L. Shek, Rachel C. F. Sun, Irene Wu and Moon Y. M. Law	
Chapter 328	Implementation of the Tin Ka Pin Project in Two Chinese Cities: Students' Subjective Outcome Evaluation	4773
	Lu Yu and Esther Y. W. Shek	
Chapter 329	Subjective Outcome Evaluation of a Service Leadership Subject: Findings Based on University Students in Hong Kong.....	4785
	Janet T. Y. Leung and Daniel T. L. Shek	
Chapter 330	Student Development under a New General Education Program in Hong Kong: A 3-Year Longitudinal Assessment.....	4799
	Daniel T. L. Shek, Lu Yu and Xiaoqin Zhu	
Chapter 331	Promotion of Service Leadership Qualities in Chinese University Students: Objective Outcome Evaluation Based on Six Waves of Data	4815
	Hildie Leung, Daniel T. L. Shek and Li Lin	
Chapter 332	Break the Cycle of Children's Environmental Health Disparities: 14th Annual Review of Program and Student Projects.....	4829
	I. Leslie Rubin, Robert J. Geller, Claire D. Coles, Victoria Green, Abby Mutic, Nathan Mutic, Wayne Garfinkel, Benjamin A. Gitterman and Joav Merrick	

Chapter 333	Natural Disasters and Vulnerable Populations: A Commentary	4851
	I. Leslie Rubin, Henry Falk and Abby D. Mutic	
Chapter 334	Barriers and Opportunities for Young Caregivers to Provide Nurturing Care in Low-Income Communities of Paraguay	4873
	Jimena Vallejos, Cassie Landers and Renata Schiavo	
Chapter 335	The Development of a Prenatal Care Health Literacy Instrument for American Indian Mothers.....	4891
	Jordyn A. Gunville and Jessica A. Williams	
Chapter 336	Breaking the Cycle of Childhood Adversity through Pediatric Primary Care Screening and Interventions: A Pilot Study	4901
	Cristian Quizhpi, Karen Schetzina, Gayatri Jaishankar, Robert Matthew Tolliver, Deborah Thibeault, Hakyong Gloria Kwak, Olushola Fapo, Jennifer Gibson, Katie Duvall and David Wood	
Chapter 337	Educating Clinic Support Staff to Enhance Early Learning Environments through Pediatric Well-Child Visits	4915
	Cori Walker, Asher Liu, Snigdha Gupta, Fuad Baroodi and Dana Suskind	
Chapter 338	Contextualizing the Social and Structural Constraints of Accessing Autism Services among Single Black Female Caregivers	4927
	Alice Hong and Jennifer S. Singh	
Chapter 339	Engaging Parents of Children with Autism Spectrum Disorder to Identify Rural Health Disparities and Factors Related to Delayed Diagnosis and Treatment	4945
	Amy A. Blumling, Susan Brasher and Jennifer Stapel-Wax	
Chapter 340	Evaluation of Health Literacy in Childhood-Onset Systemic Lupus Erythematosus Patients and Its Effect on Healthcare Utilization	4959
	Catherine Park, Traci Leong, Alexandria Wilkerson, Christy Kang, Margret Kamel, Kelly Rouster-Stevens and Roshan George	
Chapter 341	Did Medicaid Expansion Decrease Disparities for Receipt of Preventive Medical Care among Vulnerable Children?	4973
	Patricia Daniel, Audrey Leroux and Brian Barger	

Chapter 342	Self-Perceived Neighborhood Quality and Children's Depression Symptoms in a Gentrifying Northern Manhattan.....	4989
	Teresa Durham, Amy Margolis, David Pagliaccio, Wanda Garcia, Kylie Wheelock Riley, Jia Guo, Shuang Wang, Bradley S. Peterson, Virginia Rauh and Julie B. Herbstman	
Chapter 343	Water Infrastructure and Childhood Blood Lead Levels: Characterizing the Effects of Exclusion from Municipal Services in Wake County (NC, USA)	5005
	Allison C. Clonch, Michael Fisher and Jacqueline MacDonald Gibson	
Chapter 344	The Impact of Childhood Exercise and Household Income on Resilience in College Students.....	5017
	Leah Postilnik and Maeve Howett	
Chapter 345	Game-Based Learning for Positive Youth Development: A Preventive Approach	5029
	Tak-Yan Lee, Daniel T. L. Shek, Sarah S. W. Lee and Joav Merrick	
Chapter 346	The 'STREAM' Model of Digital Game-Based Learning for Enhancing Positive Youth Development among Adolescents	5039
	Tak-Yan Lee	
Chapter 347	Designing Digital Positive Youth Development Games for the Enhancement of On-and-Offline Interpersonal Relationships among Adolescents.....	5059
	Tak-Yan Lee	
Chapter 348	A Digital Positive Youth Development Game to Prevent Intrusion of Privacy.....	5075
	Tak-Yan Lee, Daniel T. L. Shek, Caroline Cheng, Robin K. H. Kwok, Tom K. C. Lui, Kam-Wing Choy, Chris Y. W. Kong and Chung-Yin Ling	
Chapter 349	A Digital Positive Youth Development Game for Promotion of Integrity in a Digital World	5089
	Tak-Yan Lee, Daniel T. L. Shek, Chris Y. W. Kong, Robin K. H. Kwok, Caroline Cheng, Tom K. C. Lui, Kam-Wing Choy, Chung-Yin Ling and Kylie K. Y. Wong	
Chapter 350	A Digital Positive Youth Development Game for Prevention of Bullying and Cyberbullying.....	5109
	Tak-Yan Lee, Daniel T. L. Shek, Chris Y. W. Kong, Caroline Cheng, Tom K. C. Lui, Kam-Wing Choy and Chung-Yin Ling	

Chapter 351	Reducing Gender Stereotypes through a Digital Positive Youth Development Game	5129
	Tak-Yan Lee, Daniel T. L. Shek, Chun-Lam Fan, Robin K. H. Kwok, Caroline Cheng, Joyce W. S. Tsang and Roger K. L. Lau	
Chapter 352	Prevention of Cognitive Biases through a Digital Positive Youth Development Game	5151
	Sarah S. W. Lee, Tak-Yan Lee, Tom K. C. Lui, Caroline Cheng and Stephen Ma	
Chapter 353	A Journey to Somewhere, to Someone: A Digital Positive Youth Development Game on Friendship and Romantic Relationship for Adolescents	5169
	Tak-Yan Lee, Sarah S. W. Lee, Tom K. C. Lui, Joyce W. S. Tsang, Caroline Cheng, Roger K. L. Lau and Kylie K. Y. Wong	
Chapter 354	A Digital Game for the Enhancement of Reflection on Materialistic and Non-Materialistic Values.....	5193
	Tak-Yan Lee, Daniel T. L. Shek and Chun-Lam Fan	
Chapter 355	Using Chinese and Western Literature in a Digital Game to Enhance Core Competencies for Peer and Romantic Relationships among Adolescents.....	5213
	Sarah S. W. Lee, Tak-Yan Lee and Chin Ma	
Chapter 356	Electronic Cigarettes: What's the Bottom Line?	5237
	U.S. Department of Health and Human Services	
Chapter 357	E-Cigarette Use among Youth and Young Adults	5243
	U.S. Department of Health and Human Services	
Chapter 358	Electronic Cigarettes: U.S. Imports in 2016	5529
	United States Government Accountability Office	
Chapter 359	Electronic Cigarettes: U.S. Imports, 2016-2018	5537
	United States Government Accountability Office	
Chapter 360	Electronic Cigarette Fires and Explosions in the United States 2009 - 2016.....	5551
	Lawrence A. McKenna Jr.	
Chapter 361	Characterization and Abuse of Electronic Cigarettes: The Efficacy of "Personal Vaporizers" as an Illicit Drug Delivery System	5589
	Michelle Peace and Joseph Turner	
Chapter 362	Outbreak of Lung Injury Associated with E-Cigarette Use, or Vaping.....	5613
	Centers for Disease Control and Prevention	

Chapter 363	Outbreak of Lung Injury Associated with E-Cigarette Product Use or Vaping: Information for Clinicians	5625
	Centers for Disease Control and Prevention	
Chapter 364	Health and the Nigerian Society: An Overview	5643
	Kehinde Kazeem Kanmodi, Ariel Tenenbaum and Joav Merrick	
Chapter 365	Opinions of Nigerian Religious Leaders and Seminarians on What Causes Cancer	5649
	Adewale I. Badru, Kehinde K. Kanmodi, Precious A. Ogundipe, Andrew M. Owadokun and Miracle A. Adesina	
Chapter 366	Awareness and Perceived Need of Nigerians on the Restorative Treatment for a Defective Tooth: A School Survey	5655
	Amidu O. Sulaiman, Kehinde K. Kanmodi and Babatunde A. Amoo

	Kehinde K. Kanmodi and Bello Almu	
Chapter 368	Do Expectant Mothers in Sokoto City Actually Want the HBV Vaccine?	5673
	Catherine Fidelis, Kehinde K. Kanmodi and Johnson Olajolumo	
Chapter 369	Prevalence of Shisha Smoking and Awareness of Head and Neck Cancer among Secondary School Students in Ibokun Town.....	5681
	Kehinde K. Kanmodi, Omotayo F. Fagbule and Timothy O. Aladelusi	
Chapter 370	Healthcare Provider Attitude towards Persons with Disabilities in Nigeria	5689
	Paul M. Ajuwon, Ishiaq O. Omotosho and Rebecca Y. Stallings	
Chapter 371	Factors Influencing the Choice of Graduating Medics in Pursuing a Medical Career with the Nigeria Defence Forces	5703
	Kehinde K. Kanmodi, Ismail O. Adesina and Abass A. Moshood	
Chapter 372	After Medical School, What Next?	5709
	Kehinde K. Kanmodi, Abass A. Moshood and Ismail O. Adesina	

Chapter 373	Barriers to Uptake of Low Vision Aids among Visually Impaired Elderly Nigerian Patients	5717
	Patrick Okonji and Darlington Ogwezzy	
Chapter 374	Attitudes of a Snowballed Sample of Nigerian Hookah (Shisha) Smokers toward Tobacco Ban	5727
	Faruk A. Mohammed, Nwafor J. Njideka, Bashar M. Aliyu, Kehinde K. Kanmodi, Omotayo F. Fagbule and Mike E. Ogbeide	
Chapter 375	The Knowledge of Drug Prescribers, Dispensers, and Administers in Sokoto Metropolis, Nigeria, on Non-Opioid Analgesics: Any Need for a Refresher Course?	5733
	Kehinde K. Kanmodi, Catherine Fidelis and Johnson Olajolumo	
Chapter 376	Neck Circumference as a Screening Instrument for Overweight and Obesity in Nigerian Secondary School Adolescents in an Urban Area	5745
	Eden E. Igbafe, Mike N. Ibeabuchi, Elizabeth E. Oyenusi, Abiola Oduwole and James Renner	
Chapter 377	Serum Triglyceride-to-High-Density Lipoprotein Cholesterol Ratio: Profile and Its Use as Surrogate for Insulin Resistance Prevalence in Overweight/Obese Adolescents	5755
	Alphonsus N. Onyiriuka, Nosakhare J. Iduoriyekemwen and Wilson E. Sadoh	
Chapter 378	Pseudohypoparathyroidism: A Rare Cause of Hypocalcaemia	5765
	Alphonsus N. Onyiriuka and Victor A. Esedume	
Chapter 379	Detecting and Preventing Wheat Stripe Rust Epidemics in Argentina	5771
	Marcelo Carmona, Francisco Sautua and Oscar Pérez-Hernández	
Chapter 380	Glycoengineering of Vaccines That Harnessing the Natural Anti-Gal Antibody Increases Immune Protection in Viral Epidemics.....	5787
	Uri Galili	
Chapter 381	The Myopia Epidemic - A Worldwide Visual Concern	5839
	Angie Wen, David MacPherson and Neesurg Mehta	
Chapter 382	Which Demographic Quintile Benefits from Public Health Expenditure in Nigeria: A Marginal Benefit Analysis	5857
	Kanayo Ogujiuba and Nancy Stiegler	
Chapter 383	Overview of U.S. Domestic Response to Coronavirus Disease 2019 (COVID-19).....	5879
	Sarah A. Lister, Kavya Sekar, Agata Dabrowska, Frank Gottron, Audrey Singer and Amanda K. Sarata	

Chapter 384	Global Economic Effects of COVID-19: In Brief.....	5903
	James K. Jackson, Andres B. Schwarzenberg, Martin A. Weiss and Rebecca M. Nelson	
Chapter 385	COVID-19: Potential Economic Effects.....	5925
	Marc Labonte	
Chapter 386	Domestic Public Health Response to COVID-19: Current Status and Resources Guide.....	5929
	Kavya Sekar and Ada S. Cornell	
Chapter 387	COVID-19 Medical Countermeasures: Intellectual Property and Affordability	5933
	Kevin J. Hickey	
Chapter 388	Coronavirus Disease 2019 (COVID-19) Poses Challenges for the U.S. Blood Supply	5939
	Jared S. Sussman	
Chapter 389	COVID-19: An Overview of Trade-Related Measures to Address Access to Medical Goods	5943
	Nina M. Hart	
Chapter 390	Development and Regulation of Domestic Diagnostic Testing for Novel Coronavirus (COVID-19): Frequently Asked Questions	5947
	Amanda K. Sarata	
Chapter 391	The Stafford Act Emergency Declaration for COVID-19.....	5959
	Erica A. Lee, Elizabeth M. Webster and Bruce R. Lindsay	
Chapter 392	Division B of the Coronavirus Aid, Relief, and Economic Security (CARES) Act— Relief for Individuals, Families, and Businesses	5963
	Molly F. Sherlock, Jane G. Gravelle, Margot L. Crandall-Hollick, Donald J. Marples and Grant A. Driessen	
Chapter 393	Overview of Initial Responses to COVID-19 by the Administrative Office of U.S. Courts and by Select Courts within the Federal Judiciary.....	5967
	Barry J. McMillion	
Chapter 394	Oversight Provisions in H.R. 6074, the Coronavirus Preparedness and Response Supplemental Appropriations Act	5971
	Ben Wilhelm	
Chapter 395	H.R. 6201: Paid Leave and Unemployment Insurance Responses to COVID-19	5975
	Sarah A. Donovan, Julie M. Whittaker and Katelin P. Isaacs	

Chapter 396	Tax Credit for Paid Sick and Family Leave in the Families First Coronavirus Response Act (H.R. 6201) (Updated)	5979
	Molly F. Sherlock	
Chapter 397	Workplace Leave and Unemployment Insurance for Individuals Affected by COVID-19	5983
	Julie M. Whittaker, Sarah A. Donovan and Katelin P. Isaacs	
Chapter 398	COVID-19: Social Insurance and Other Income-Support Options for Those Unable to Work	5987
	Laura Haltzel, Katelin P. Isaacs, William R. Morton, Elizabeth A. Myers, Scott D. Szymendera and Julie M. Whittaker	
Chapter 399	COVID-19 Economic Stimulus: Business Payroll Tax Cuts	5991
	Molly F. Sherlock and Donald J. Marples	
Chapter 400	Tax Cuts and Economic Stimulus: How Effective Are the Alternatives?	5995
	Jane G. Gravelle	
Chapter 401	Payroll Tax Cuts as an Economic Stimulus Response to Coronavirus Disease (COVID-19)	6003
	Donald J. Marples and Molly F. Sherlock	
Chapter 402	Federal Executive Agencies: Hiring Flexibilities for Emergency Situations	6007
	Barbara L. Schwemle	
Chapter 403	SBA Economic Injury Disaster Loans for COVID-19	6011

	John Frittelli	
Chapter 405	The Financial Industry and Consumers Struggling to Pay Bills during the COVID-19 (Coronavirus) Outbreak	6017
	Cheryl R. Cooper	
Chapter 406	Federal Reserve: Recent Actions in Response to COVID-19	6021
	Marc Labonte	
Chapter 407	COVID-19 and Stimulus Payments to Individuals: Considerations on Using Advanced Refundable Credits as Economic Stimulus	6025
	Margot L. Crandall-Hollick	
Chapter 408	COVID-19 and Stimulus Payments to Individuals: Summary of the 2020 Recovery Rebates in the CARES Act (S. 3548)	6029
	Margot L. Crandall-Hollick	

Chapter 409	COVID-19 and Stimulus Payments to Individuals: How the 2009 Economic Recovery Payment Worked.....	6033
	William R. Morton	
Chapter 410	COVID-19 and Stimulus Payments to Individuals: How Did the 2008 Recovery Rebates Work?.....	6037
	Margot L. Crandall-Hollick	
Chapter 411	COVID-19 and Stimulus Payments to Individuals: Potential Impacts of Direct Payments on Family Incomes.....	6041
	Conor F. Boyle and Jameson A. Carter	
Chapter 412	COVID-19 and Direct Payments to Individuals: Historical Precedents.....	6045
	Gene Falk	
Chapter 413	COVID-19: Cybercrime Opportunities and Law Enforcement Response	6047
	Kristin Finklea	
Chapter 414	COVID-19 and Broadband: Potential Implications for the Digital Divide.....	6051
	Colby Leigh Rachfal	
Chapter 415	COVID-19: Potential Role of Net Operating Loss (NOL) Carrybacks in Addressing the Economic Effects.....	6055
	Mark P. Keightley	
Chapter 416	USDA Domestic Food Assistance Programs' Response to COVID-19: House-Passed H.R. 6201 and Related Efforts	6059
	Randy Alison Aussenberg and Kara Clifford	
Chapter 417	COVID-19: The Potential Role of TANF in Addressing the Economic Effects	6063
	Gene Falk	
Chapter 418	COVID-19 at a Glance: From Health, Education, Economic, to Science and Technology in South East Asia and India.....	6067
	Asep Bayu Dani Nandiyanto, Tryastuti Irawati Belliny Manullang, Rina Maryanti, Amir Machmud, Ana and Asnul Dahar Minghat	
Chapter 419	A Glimpse of the Pandemic COVID-19 Outbreak around the Globe.....	6071
	Paulami Ghosh, Deepanmol Singh, Arnab Mondal and Surajit Mondal	
Chapter 420	The COVID-19 Pandemic in Indonesia	6079
	Andika Chandra Putra	
Chapter 421	What We Learn When We Are Facing COVID-19 in Indonesia	6089
	Tryastuti Irawati Belliny Manullang, Asep Bayu Dani Nandiyanto, Ace Suryadi, Endang Rochyadi and Dingding Haerudin	

Chapter 422	COVID-19 Outbreak and the Steps Taken by India	6097
	Paulami Ghosh, Arnab Mondal, Deepanmol Singh and Surajit Mondal	
Chapter 423	Bayanihan Values during COVID-19	6107
	Brando Cabigas Razon and Tryastuti Irawati Belliny Manullang	
Chapter 424	Stress of the Changes in the Life and Conditions of Patients.....	6115
	Mariam R. Arpentieva, Asnul Dahar Minghat and Gulzhaina K. Kassymova	
Chapter 425	COVID-19 Possible Treatment through Exercise and Nutrition.....	6125
	Hamidie Ronald Daniel Ray and A. Firmansah Wargahadibrata	
Chapter 426	Changes and Transformations in Human and Social Life: Anticipation and Understanding of Events and Stresses.....	6133
	Asnul Dahar Minghat, Mariam R. Arpentieva Danat Zh. Zhanatayev and Gulzhaina K. Kassymova	
Chapter 427	Adjustment of Thai Curriculum and Instruction in the COVID-19 Crisis	6145
	Sutthiporn Boonsong	
Chapter 428	Education and Information about COVID-19 for Improving Students with Special Needs Knowledge in Indonesia.....	6153
	Rina Maryanti, Asep Bayu Dani Nandiyanto, Achmad Hufad and Sunardi	
Chapter 429	Increasing the Science Process Skills Using Virtual Science Laboratory during the COVID-19 Pandemic.....	6163
	Ida Hamidah	
Chapter 430	Post Covid-19 Competencies of Teachers	6173
	Sujin Nukaew, Sangrung Poolsuwan and Rossarin Jermtaisong	
Chapter 431	Perspectives of Thai Parents on Covid-19 Outbreak That Effects Students Learning.....	6181
	Sutthiporn Boonsong and Klairung Rabieboat	
Chapter 432	Challenges and Chances in Learning Management for Thai Students during the Covid-19 Outbreak.....	6187
	Rossarin Jermtaisong, Sangrung Poolsuwan and Sujin Nukaew	
Chapter 433	The Role of Malaysian School Administrators in Facing Movement Control Order during Covid-19	6195
	Nazeri Mohammad and Siti Ilyana Mohd Yusof	
Chapter 434	New Norms in the World of Education: Think Out of the Box from Malaysian School Administrator's Perspective during Pandemic	6201
	Nazeri Mohammad and Arshad Jais	

Chapter 435	The Global Impacts of COVID-19: Risk and Crisis Management in Affected Company.....	6209
	Eddy Soeryanto Soegoto and Senny Luckyardi	
Chapter 436	The Impact of COVID-19 on the Indonesian Economy.....	6221
	Amir Machmud	
Chapter 437	Consumer Purchasing Patterns in Response to COVID-19 Pandemic in Indonesia.....	6227
	Puspo Dewi Dirgantari, Yusuf Murtadlo Hidayat, Rury Nugraheni and Mohd Halim Mahphoth	
Chapter 438	Analysis of the Application of the Mobile Vending Machine as a Distribution Tool for COVID-19 Basic Protective Assistance for the Indonesian Society	6235
	Bachrul Tias, Cahyanisa Alifa Pramesti, Cuk Khim, Muhammad Shofwan Qobus, Salma Salsabila, Sri Anggraeni, Dian Usdiyana and Asnul Dahar Minghat	
Chapter 439	Health Truck Mobile Community Health Services for COVID-19.....	6247
	Anjani Nurfitriana, Dea Puspha Annisa, Fitria Faizah Hilman, Sri Anggraeni, Dian Usdiyana and Asnul Dahar Minghat	
Chapter 440	Automatic Slit for Delivering Food Aid to Workers and Medical Personnel in Motorized Vehicles	6255
	Ghina Mufidah, Thyta Medina Salsabila Erlangga, Hasna Nadaa Fida Karima, Fitria Felashopa, Sri Anggraeni and Asnul Dahar Minghat	
Chapter 441	Mobile Food Truck to Assist People's Food Fulfillment during the COVID-19 Pandemic in the Large-Scale Social Restrictions Area	6263
	Wafa Raihanah Arwa, Muhammad Rayhan Fadillah, Nabila Nurul Anisa Az Zahra, Imam Imadudin, Sri Anggraeni and Asnul Dahar Minghat	
Chapter 442	Mini Helicopter as Disinfectant Sprayer (Hypochlorous Acid).....	6273
	Aulia Rachmah, Fauzia Utami Malik, Rully Ilham Pratama, Shalma Nurlatifah, Sri Anggraeni and Asnul Dahar Minghat	
Chapter 443	Modification of Public Transportation to Prevent the Spread of COVID-19 in West Java, Indonesia.....	6283
	Putri Sakinah Hanafi, Asita Puji Astuti, Fajar Miraz Fauzi, Gabriela Chelvina Santiuly Girsang, Sri Anggraeni and Asnul Dahar Minghat	
Chapter 444	Microfluidic Devices in PCR System for the Application of COVID-19 Rapid Detection	6291
	Budi Mulyanti and Roer Eka Pawinanto	

Chapter 445	Community Service during COVID-19 Pandemic at Universitas Pendidikan Indonesia.....	6307
	A. Ana, Asep Bayu Dani Nandiyanto, M. Syaom Barliana, Iwa Kuntadi, Dedi Suryadi, Vina Dwiyantri and M. Muktiarni	
Chapter 446	Simulation of Multi-Hop Routing Wireless Sensor Network Topology Performance and Its Advantages during COVID-19 Pandemic.....	6315
	Lilik Hasanah, Heru Yuwono, Ahmad Aminudin and Budi Mulyanti	
Chapter 447	COVID-19 and the Rise of Telemedicine and Integrative Medicine: Benefits and Challenges.....	6325
	Wilfred W. K. Lin	
Chapter 448	Role of Telemedicine in COVID Times for Neurologists and Neurosurgeons	6331
	Sanjam Narang, Summit Bloria, Vishwanatha and Harish Chandrappa	
Chapter 449	COVID-19 Outbreak Represents an Opportunity for the Development of Internet Healthcare.....	6339
	Huan Wang, Lin Sun, Mei Gao, Lingxia Cao, Weixia Liu, Menghan Gao, Guixia Wang and Chenglin Sun	
Chapter 450	Arrhythmias in COVID-19 Patients: Benefits and Challenges When Using Telemedicine	6355
	Mariana Floria, Ioana Maria Ceomîrtan-Negrii, Elena Diana Năfureanu, Elena Mihaela Cărauşu and Ileana Antohe	
Chapter 451	Legal Ethical Dilemmas Related to the Care of COVID-19 Patients through Telemedicine.....	6383
	José Antonio García Pereáñez and David Alberto García Arango	
Chapter 452	Epidemiology and Pathogenesis of COVID-19.....	6389
	Seda Salman Yilmaz and Gökhan Aygün	
Chapter 453	Transmission of SARS-COV-2 and Prevention Strategies.....	6399
	Bilgul Mete, Ahmet Furkan Kurt and Gokhan Aygun	
Chapter 454	Clinical Aspect of COVID-19.....	6411
	Aslıhan Demirel and Fehmi Tabak	
Chapter 455	Diagnosis of COVID-19	6431
	Mert A. Kuskucu and Fehmi Tabak	
Chapter 456	Treatment Options for COVID-19 Patients	6439
	Hakan Yavuzer and Pınar Arman	
Chapter 457	Intensive Care Management of COVID-19 Patients.....	6453
	Olca Dilken and Yalim Dikmen	

Chapter 458	Anatomical Basis of the COVID-19.....	6463
	Mehmet Üzel and Ö. Alp Taştan	
Chapter 459	Genetic Background of Differences in the Incidence of Corona Virus Infection	6477
	R. Dilhan Kuru and İlhan Onaran	
Chapter 460	The Clinical Course of COVID-19 in Elderly Patients.....	6499
	Hakan Yavuzer and Rabia Bag Soytas	
Chapter 461	SARS COV-2 in Pediatric Patients: Hematological Face of the Disease.....	6513
	Tulin Tiraje Celkan and Ayşe Gonca Kacar	
Chapter 462	COVID-19 and Ophthalmology	6531
	Ceyhun Arici and Burak Mergen	
Chapter 463	The Impact of the COVID-19 Pandemic on Patients with Diabetes	6547
	Zeynep Mine Coskun and Sema Bolkent	
Chapter 464	The Impact of COVID-19 Pandemic on the Patients with Chronic Respiratory Diseases	6559
	Buket Caliskaner Ozturk	
Chapter 465	The Impact of the COVID-19 Pandemic on Patients with Cardiovascular Diseases	6573
	Serap Yavuzer and Veysel Suzan	
Chapter 466	The Impact of the COVID-19 Pandemic on Cancer Patients	6585
	Hande Turna	
Chapter 467	COVID-19 from General Surgery Perspective.....	6595
	Selen Soylu and Serkan Teksoz	
Chapter 468	Cytokine Storm and Oxidative Stress in Severe COVID-19	6603
	Yildiz Dincer and Selin Yuksel	
Chapter 469	Antioxidant Agents in the Treatment of COVID-19.....	6613
	Mujgan Cengiz	
Chapter 470	Vaccine Development Studies for COVID-19.....	6627
	Yesim Tok and Gökhan Aygün	
Chapter 471	Molecular Approaches in COVID-19 Treatment.....	6635
	Mehmet Güven and Bahadır Batar	
Chapter 472	Overview of U.S. Domestic Response to the 2019 Novel Coronavirus (2019-nCoV)	6649
	Sarah A. Lister, Frank Gottron, Kavya Sekar, Audrey Singer and Agata Dabrowska	

Chapter 473	Another Coronavirus Emerges: U.S. Domestic Response to 2019-nCoV	6665
	Sarah A. Lister and Kavya Sekar	
Chapter 474	The Coronavirus: U.S.-China Economic Considerations.....	6669
	Karen M. Sutter and Michael D. Sutherland	
Chapter 475	The Wuhan Coronavirus: Assessing the Outbreak, the Response, and Regional Implications	6673
	Jennifer B. Nuzzo	
Chapter 476	What You Need to Know about Coronavirus Disease 2019 (COVID-19)	6685
	Department of Health and Human Services	
Chapter 477	Coronavirus Disease 2019 (COVID-19) Situation Summary	6689
	Centers for Disease Control and Prevention	
Chapter 478	Science and Tech Spotlight: Coronaviruses	6697
	Timothy M. Persons	
Chapter 479	COVID-19: Current Travel Restrictions and Quarantine Measures	6703
	Edward C. Liu	
Chapter 480	COVID-19: Federal Economic Development Tools and Potential Responses	6707
	Michael H. Cecire

"Fill with mingled cream and amber,
I will drain that glass again.
Such hilarious visions clamber
Through the chamber of my brain —
Quaintest thoughts — queerest fancies
Come to life and fade away;
I am drinking ale today."
Edgar Allan Poe (1809-1849)

INTRODUCTION

Alcohol can be traced back to the neolithic period in human history which was the last period in the Stone Age of homo sapiens; during this truculent time ancient humans developed agriculture and utilized polished stone tools [1]. Ale is one of oldest liquids produced by humans dating back in the 5th millennium BCE; beer dates back to at least 3000 BC [2]. Alcohol was an important source of clean hydration for millennia when uncontaminated water was hard to find—even in modern times [3]. As noted by the famous French chemist and microbiologist of the 19th century who saved the wine industry: “*Wine is the most healthful and most hygienic of beverages.*” (Louis Pasteur: 1822-1895).

The Old Testament notes that wine “gladdens” the heart (Psalm 104:15), but also warns of the dangers of overuse of alcohol (Proverbs 20:1—10th century BCE) that includes poverty, strife, and injustice (Proverbs 23:20-21; 23:29-30; 31:4-5). Wine was prominently mentioned in the New Testament in the first century AD such as being used at weddings (John 2:3) or being associated with drunkenness and debauchery (Ephesians 5:18). Moderation in wine drinking was also linked to improved health (1 Timothy 5:23). Alcohol has been both celebrated and denounced by famous human beings for thousands of years.

“Alcohol may be man’s worst enemy, but the Bible says love your enemy.”
Frank Sinatra (1915-1998)

PREVENTION

We desperately need guidance in learning how to prevent alcohol and drug addiction in our youth and establish prevention programs to decrease the devastating toll it has and will take on billions of human beings in this century and beyond. We must be concerned and more cognizant about addiction and its effect on our youth including their alarming use of nonmedical analgesics. It is important to study youth in their communities and thus support more community-based research protocols [4]. It is useful to know what is positive in substance abuse management as well as what is not [5, 6].

PREDICTORS

Excessive drinking in adolescence can be a social and public health problem (violence, poor or missing school performance, drunk driving, suicide and risky sexual behavior as some examples) and prediction as well as prevention or abatement of adverse effects have both clinical and public health value.

Researchers [7] from the University of California San Diego School of Medicine have identified 34 neural factors that can predict adolescent alcohol consumption. Their study is a prospective investigation that used machine learning with demographic, neurocognitive, and neuroimaging data in substance-naive adolescents to predict alcohol use initiation by age 18 years.

There were 137 healthy substance-naïve adolescents aged 12-14 years in the study, who underwent neuropsychological testing and structural and functional magnetic resonance imaging (sMRI and fMRI), and then were followed annually.

At the age of 18 years, 70 out of the 137 (51%) started moderate to heavy alcohol use, while 67 remained non-users. The researcher used all the collected data to create a model containing predictors contributing to alcohol use by age 18 years:

- They were male with a higher socioeconomic background
- They reported dating, possessed more externalized behaviors, such as lying or cheating and believed alcohol would benefit them in social settings
- They performed poorly on executive function tests
- Their neuroimaging results indicated thinner cortices - the outer layer of neural tissue covering the brain

In this study neuropsychological, sMRI, and fMRI data increased the prediction accuracy of the model. Now the question is how to use this data in the clinical and everyday use of health professionals to predict, intervene and prevent excessive alcohol consumption in adolescence.

IMPRINT OF GENETICS

“We can do genetics. We can do experiments on fruit flies. We can do experiments on yeast. It’s not so easy to do experiments on humans. So, in fact, it helps us, to interpret our own genetic code, to have the genetic code of the other species.”

Craig Venter (b: 1946)

Alcohol use disorder is a complex condition with major underlying factors that involve one’s environment and genetic background [1]. Genetic components have been found to be highly contributory in some persons’ struggles with alcohol consumption [1, 8]. Genetic studies that have provided some insight into genetic features in these persons include candidate gene research, linkage research, twin studies, and genome-wide association studies (GWAS) [9].

Alcohol use disorder is found in some families and genetic factors account for 40% to 60% of this phenomenon that includes increase risk in monozygotic twin studies (versus the dizygotic twin) [10, 11]. The alcohol dehydrogenase gene cluster can lead to alcohol dependence in some persons while genes of alcohol metabolism (alcohol dehydrogenase [ADH] and aldehyde dehydrogenase [ALDH]) are protective [8, 9, 12].

Using genome-wide association studies (GWAS) some genes associated with alcohol dependence have also been linked with other substance abuse disorders [1, 8]. An example is that a number of genes in the gamma-aminobutyric acid-ergic system can increase the risks for nicotine dependence while changes in cadherin 13 may lead to methamphetamine dependence [13, 14]. Use of GWAS is aiding in finding new genes implicated in increasing risks for a person developing alcohol use disorder [1]. Another unique approach is to look at collections of data from state databases and use this so-called “big-data” tool to help identify

factors in the environment-genetics interaction in persons leading to problematic alcohol use [15].

Other genes under study include GABRA2 as well as alcohol dehydrogenases 1B and 4 [16]. Studies in adolescents have suggested that alcohol use disorder may be linked to certain circadian rhythm genes: NR1D1 and BHLHE41 [11]. Another gene of current interest is the GRIN2B gene that is linked to glutamatergic signalling and possible effects on alcohol use disorders via changes in the posterior cingulate cortex [17].

Also, ASTN1 (astrotactin neuronal protein) is a gene linked with alcohol dependence that is involved in glial-guided neuronal migration and has been linked by research to attention-deficit, hyperactivity disorder, autism spectrum disorders, bipolar disorder, and schizophrenia [8, 18]. Research also has seen a link between SNPs (single nucleotide polymorphisms) in the gene C15orf53 (located on chromosome 15q14); the number of alcohol-related symptoms and the greater number of alcohol symptoms leads to a higher chance of having a variant in this gene [19]. Variations in this gene may lead to augmented risks for bipolar disorder, a condition considered co-morbid with alcohol dependence [20].

CONCLUSION

What has emerged from 20th and now 21st century investigations is that alcohol use disorder is a neurobiologic-genetic disorder (brain disease) with different types such as the proposed Cloninger type 1 (harm avoidance type) with decreased dopamine and increased serotonin as well as type 2 (novelty seeking) with decreased serotonin [21]. The search for reliable biomarkers for this disorder (as healthful harbingers) will continue such as decreased platelet MAO activity, alcohol-induced dopamine (DA) release, measures of central glutamate levels, and studies using positron emission tomography of functional MRI as well as central glutamate tone using MR spectroscopy [22, 23].

Environment factors that intrinsically influence the development of alcohol use disorder that are under study include one's family milieu, exposure to childhood adversity, culture, and religion [24]. Further research will continue to overcome current inpasses and cul de sacs of ignorance in the complex interplay of one's milieu and genetics in the development of alcohol use disorder; such incessant, intrepid inquires involve animal work (i.e., rat models) and epigenetic studies (i.e., alterations and aberrations in DNA methylation and chromatin structure) [25-30]. The guidance of the U.S. National Institute on Alcohol Abuse and Alcoholism (NIAAA) has been important for nearly half a century in this exigent effort [30]. Such astute auspices is critical as clinicians and society saliently seek to circumspectly protect its children, adolescents, and adults from the doleful, deleterious dilemmas and cumbrous consequences of alcohol use disorder in the 21st century.

"I would not put a thief in my mouth to steal my brains."
William Shakespeare (1564-1616)

Chapter 2

THE IMPACT OF EXPOSURE TO ALCOHOL ADVERTISEMENTS ON ADOLESCENTS: A LITERATURE REVIEW

***Marye Margaret Boggs, MPH
and Praveen Durgampudi*, MBBS, MPH***

Department of Public Health and Preventive Medicine,
St. George's University School of Medicine,
St. George's, Grenada, West Indies

ABSTRACT

Alcohol consumption occurs worldwide and widespread among youth. Although, alcohol was once given to children as it was cleaner than water, neurological research continues to inform individuals of the toxicity of alcohol on the brain. The topic of interest is the subtle relationship between exposure to alcohol advertisements and alcohol consumption in children. The purpose of this literature review was to determine the current perception held by researchers concerning the relationship between exposure to alcohol advertisements and alcohol consumption by adolescents. Google scholars search engine was used to select published peer-reviewed journal articles related to the topic. The body of literature suggests exposure to alcohol advertisements does influence alcohol consumption among children around the world, including the United States, Germany and Australia. More specifically, increased exposure influences alcohol consumption by altering perceptions of alcohol. These findings indicate educating children and parents about the negative effects of alcohol on the developing child needs to begin at the start of secondary school. Although measuring the impact of exposure to alcohol advertisements is difficult, as technology advances, researchers in the fields of public health and neuroscience may be able to examine the subtle relationship between alcohol advertising and alcohol consumption more thoroughly. In addition, regulating alcohol advertisement content, location, and frequency to limit children's exposure is an ideal progressive policy reform that will serve to protect children.

INTRODUCTION

Alcohol consumption is a key component of cultures and economies around the world. The historical acceptance of alcohol use among cultures enables this substance's consumption in every country around the globe at almost any age [1]. The impacts of alcohol consumption on individual health and society at large make alcohol consumption a public health concern. The acceptance of alcohol consumption by society contributes to alcohols frequent promotion and alcohols frequent promotion contributes to alcohol's generational acceptance in society despite known health disadvantages of heavy consumption [2].

The long-term consequences of alcohol consumption during human development appears not to be communicated as well as the benefits of alcohol consumption as approximately 1-4% of infants are born with fetal alcohol syndrome [3, 4] and adolescents binge drink more than previous generations [5]. The health impacts of alcohol in adulthood are associated with age of consumption. The prevalence of alcohol abuse disorders among individuals who first consumed at age 12 years is 40% whereas the prevalence among individuals who first consumed at age 18 years is 16% [6].

A larger number of youth report heavy drinking compared to adults ranging from 50% of 12-14 year olds and 79% of 17-18 year olds [7]. Although the trends of binge drinking slightly differ by age and ethnicity, approximately 27% of 14-18 year-old males participate in binge drinking compared to 15% of females [5]. This is not just an American issue. A cross-sectional study of 13 year-old students in 6 European countries determined 27% reported consuming five or more alcoholic beverages at least once in their lives [8].

Alcohol consumption in general—especially binge drinking-- in children is a health risk for each child and others as alcohol consumption increases risky behavior [9]. Alcohol consumption by children increase the risk they will miss school, experience social (aggression), physical (headaches), and neurological problems (slowed memory, abnormal brain growth), abuse other drugs, partake in unprotected sexual activity, and die from alcohol poisoning. Alcohol consumption is a leading cause of disability [1] and the cause of avoidable injuries and deaths [1]. Underage drinking is related to the three leading causes of death among individuals aged 12-20 years, which are unintentional injury, homicide, and suicide [9].

Early adolescence is a critical period when the majority of individuals initiate alcohol consumption for a variety of reasons: primarily social [10]. Rarely do adolescents drink alone. A larger number of youth engage in alcohol consumption around other youth who are consuming alcohol. Youth aspire to drink to achieve euphoria from the sensation of breaking laws, social experience of drinking in a group, expectation of experiencing a positive emotional state [10]. Understanding that these perceived benefits of alcohol are not the only impacts of alcohol on society is important to convey to youth.

Although at the appropriate ages and doses alcohol consumption is relatively harmless, alcohol advertisements do not consistently convey this information to viewers. Children do not have the mental capacity to understand that marketing techniques are designed to persuade and manipulate viewers into becoming consumers [11]. The health risks and unique

vulnerabilities of children are overshadowed and underestimated by children due to the high influx of positive portrayals of alcohol consumption compared to realistic portrayals in advertisements [12].

The effects of alcohol exposure on the developing fetal brain are well documented under the spectrum of fetal alcohol syndromes [13]. Alcohol exposure in utero is one of the known preventable causes of a permanent intellectual disability. Due to the fact alcohol consumption by adolescents is commonly occurring without obviously disabling deficits; the effects of alcohol consumption on the adolescent brain were thought to be less significant until recent decades. The brains of children, just like the developing fetuses, are more vulnerable to the effects of alcohol compared to the mature brain. Neurological changes due to alcohol exposure are broadly predicted by two main behavioral patterns: early initiation of alcohol consumption and binge drinking during adolescence [14]. One beer will circulate in an adolescent's body at a much higher concentration than in a fully developed adult's body making smaller quantities of alcohol more toxic to developing children.

Human brains rapidly increase in size in the womb and in the first three years of life [15], but the second decade of life is important for improving the efficiency of the brain. Connections between neurons are strengthened and excess tissue is trimmed away in the normal developing brain. The brain naturally undergoes this process called "pruning" so that it relies on fewer important connections and can function with a higher speed of processing and accuracy. Research suggests that consistent consumption of alcohol from age 11-14, not only prevents the ability of the brain to prune itself [16], but increases a child's risk of developing alcohol dependent behaviors and suffering from the cognitive effects of neurodevelopmental delays, such as slowed cognition and impaired ability to control behavior [16].

Some adolescents may have a genetic predisposition to suffering from neurological changes from alcohol [16]. A study of monozygotic twins further disclosed some of the neurotoxic damages of alcohol exposure and potential inborn neurological differences that may increase risk for developing alcohol abuse disorders [17]. The study of twins revealed brain regions that were susceptible to neurotoxic damage in adolescents. The areas included the ventral diencephalon and middle temporal gyrus. These brain regions are important for processing sensory and motor information and emotions and memories, respectively.

Despite the health concerns for adolescents, they are frequently targeted and exposed to a high number of alcohol advertisements. Anderson, de Bruijn, Angus, Gordon and Hastings [17] discuss data demonstrating that children are more susceptible to the messages of alcohol advertisements compared to adults because they are inexperienced. The most common forms of alcohol advertisements encountered include television, billboard, poster, magazine, and radio. The Internet is also becoming a popular way to target youth with advertising as well [11]. The content of alcohol advertisements directed at youth, is a subject of concern. A five-year study of alcohol advertisements in American youth magazines revealed that one fourth of the alcohol advertisements, mainly beer and spirits, targeting youth sent messages with underlying sexual messages [18]. Interestingly, these underlying messages align with youth behaviors associated with alcohol consumption.

The content is more appropriate for an adult audience, yet is reaching many naive adolescents. Winter, Donaven, and Fielder [19] found that Australian adolescents ages 13-17 were exposed to the same number of alcohol advertisements as individuals 18-24, which was 75% of the advertisements viewed by 25 year-old individuals. In the United States, exposure

to alcohol advertisements increased for 18-20 year olds from 2005-2011 more than any other age group targeted by companies selling beer and spirits [20]. The tendency of the alcohol industry to target a vulnerable population suggests they are benefiting from the investment, which is a concern.

The hypothesis of this study was that alcohol advertisements do impact adolescents' choices to consume alcohol for the first time and to continue consuming alcohol. The purpose of this literature review was to determine the current perception held by researchers concerning the relationship between exposure to alcohol advertisements and alcohol consumption by children.

Goals

The goal of this literature review was to report a generalizable consensus on the relationship between alcohol advertisement exposure and alcohol consumption in adolescents to spread awareness and encourage action. To accomplish the goal, three objectives were established. The three objectives were to 1) review literature of published journal articles investigating the relationship between alcohol advertisement exposure and initiation of alcohol consumption and overall alcohol consumption in adolescents and 2) assess youths' reported perceptions of alcohol 3) assess other factors reported to influence alcohol consumption among adolescents. Key terms:

- Adolescent: individual between ages 10-19
- Youth: individual between the ages 20-26
- Alcohol advertisement: any form of communication that promotes alcohol consumption (e.g., individual drinking, posters, magazines, commercial).

METHODS

Google Scholars search engine was used to select published peer-reviewed journal articles related to the topic of interest. Google Scholars selects articles from search engines across the major academic fields including Public Health, Medicine, Neuroscience, Psychology, Anthropology, and many others. This enables a broad and thorough literature search that is not limited by the literature accessible through specific field-based search engines. In order to provide an understanding of the recent literature, articles were excluded if they were published—prior to 2005-- more than ten years ago. Articles published within the last seven years were preferentially chosen to the older articles to focus on current literature.

To search the literature regarding exposure to alcohol advertisements and alcohol consumption by adolescents, phrases such as “exposure to alcohol advertisements and age of consumption”, “exposure to alcohol advertisements and alcohol consumption among minors”, “impacts of alcohol advertisement exposure on children” were typed into the search engine.

To gather information on youths' perceptions of alcohol and alcohol consumption, phrases such as “youth's perceptions of alcohol”, “adolescents' beliefs about alcohol”, “adolescents' beliefs about alcohol consumption” were searched. Educational interventions

were searched using the same techniques. Phrases such as “alcohol education and consumption among minors”, “alcohol educational interventions for children”, “and impact of alcohol education on children” were searched in Google Scholars.

Fourteen published primary articles were chosen for review. The studies were completed in countries (Germany, Australia, New Zealand, United States) with a high rate of alcohol consumption among youth and high rate of alcohol advertisements. Longitudinal and cross-sectional study designs were included. The majority of the participants in each study were between the ages of 11 and 20 years. One study looked at children between the ages of 15 and 25 years.

Literature Analysis

Exposure to alcohol advertisements impacts adolescents’ preferences for alcohol and subtly encourages consumption. Caswell [21] found a positive correlation between exposure to alcohol advertisements and liking alcohol advertisements. In addition, the level of exposure to alcohol advertisements was more predictive of alcohol consumption for adolescents that reported liking the advertisements.

Whether or not some individuals are more inclined to like the advertisements by nature or if the advertisements are inherently attractive is a question researchers are trying to answer. Alcohol advertisements influence alcohol consumption in youth by associating desired outcomes, popular idols, and role models with alcohol consumption. Associating role models of adolescents and alcohol sends an underlying message to children that consuming alcohol is not only an acceptable activity, but also an enjoyable activity.

Moreover, Chen et al. [22] found a relationship between alcohol advertisement content and the development of positive expectations regarding alcohol consumption. Positive reactions to alcohol advertisements that target their audiences with humor, popular idols, and songs were positively related to adolescents’ intentions to purchase and consume alcohol. Although this study only related alcohol advertisements to the intentions of adolescents to drink alcohol and not alcohol consumption itself, the impact of alcohol advertisements on the intentions of adolescents is a subtle change in cognition.

Morgenstern et al. [23] found that attitudes toward alcohol consumption change in German youth, as they grow older and may mediate the effects of alcohol advertisements. At the follow up of the non-drinking German youth, 28% of the non-drinkers were current drinkers. In addition, 46% of the students reported more positive attitudes toward alcohol consumption. Only 15% of the participants reported less positive attitudes toward alcohol.

Ellickson, Collins and Hambarsoomians [2] investigated the relationship between exposure to in-store alcohol advertisements and alcohol consumption in a prospective cohort study of seventh grade South Dakotan students. For seventh grade non-drinking students, alcohol consumption in grade nine was predictable based on exposure to in-store alcohol advertisements. For seventh graders already consuming alcohol, exposure to magazines with alcohol advertisements and beer concession stands at sports or music events predicted frequency of alcohol consumption in the ninth grade. This study suggests that there is a possibility different forms of advertising uniquely influence different groups of children.

Collins et al. [27] conducted a longitudinal study of 11-12 year-old students in South Dakota to determine if there were any positive relationships between exposure to forms of alcohol advertisements and the students' odds of drinking within the past year. Collins et al. [27] found that 20% of the non-drinking fifth grade students in the 75th percentile of exposure to alcohol advertisements reported alcohol consumption by the seventh grade. Only 13% of the non-drinking fifth grade students in the 25th percentile of exposure to alcohol advertisements reported drinking in the seventh grade.

Snyder et al. [25] compared exposure to alcohol advertisements and industry data on the amount of money spent on alcohol advertisements with the number of alcoholic drinks consumed in the past month by individuals between the ages of 15-26. The results indicated that for each additional alcohol advertisements viewed in the previous month, the number of drinks consumed by individuals less than twenty years old increased by one percent. In addition, each additional dollar spent on alcohol advertisements increased overall alcohol consumption by 2.8 percent.

Henewinkel and Sargent [8] studied fifth through ninth grade students in Germany to examine the relationship between exposure to alcohol use in movies and initiation of alcohol consumption in this age group. Thirty-three percent of the participants initiated alcohol consumption without informing their parents and 14% were, at the point, binge drinking. The results of this study revealed that the mean exposure to alcohol advertisements in movie was 3.2 hours. Students were categorized into four different quartiles based on exposure to alcohol advertisements in movies. As exposure to alcohol advertisements increased, the risk ratio for initiation of alcohol consumption without parental knowledge and engaging in binge drinking increased.

Grenard, Dent, and Stacy [26] investigated exposure to alcohol advertisements, alcohol consumption and alcohol related problems in adolescents. Even after controlling for many covariates (drinking by peers, drinking by close adults, playing sports, parents' education, and others), alcohol ad exposure and liking of the ad in seventh grade predicted participants' alcohol consumption in ninth grade and alcohol use problems. This study suggested that, for some adolescents, alcohol advertisements are one of the major factors encouraging more alcohol consumption by youth and which ultimately lead to alcohol use problems. One factor contributing to consumption by adolescents may be that the alcohol advertisements of popular brands consumed by the age group are more appealing to them compared with the advertisements of unpopular brands [27].

Literature indicates alcohol advertisements on television, in-stores, and on the radio are not the only forms of advertising children notice. Pasch et al. [28] found that as exposure to alcohol advertising near schools increases the intention to drink increases as well. Pasch et al. [28] and Feighery et al. [29] both investigated the relationship between owning alcohol promotional items with adolescent alcohol consumption. Feighery et al. [29] found that two-thirds of the 11-14 year-old students reported weekly visits to retail stores in which alcohol advertisements were noticeable. Both exposure to alcohol advertisements in stores and possessing alcohol promotional items were associated with greater odds of ever drinking alcoholic beverages [29]. Moreover, the children who indicated they own alcohol promotional items were 1.5 times more likely to currently consume alcohol [29].

As the Internet continues to emerge as a platform for youth activities and an unlimited source of exposure to any type of advertisement, investigations on the impact of online alcohol advertisements determined that online alcohol advertisements are powerful marketing

tools for youth. Lin et al. [30] found that exposure to online alcohol advertisements increased 13-14 year olds' odds of drinking by 98% whereas exposure to offline (posters, television, radio) alcohol advertisements only increased the odds of alcohol consumption by 51%. Combined exposure to online alcohol advertisements and offline advertisements increased consumption among children already drinking [30]. In a cross-sectional study of Australian boys aged 12-15 years, similar results to Lin et al. [30] were found regarding the impact of alcohol advertisements and alcohol consumption. Jones and Magee [31] found exposure to alcohol advertisements on the Internet was associated with current alcohol consumption among the male youth. Interestingly exposure to alcohol advertisements in venues where alcohol is consumed (e.g., bars) was associated with alcohol consumption within the last year. When male youth were exposed to alcohol advertisements in bars and online, there was an association with alcohol consumption within the last month. This article suggests that exposure to online advertisements potentiates the effects of exposure in public areas of consumption.

Additional Influences

Many factors are involved in an adolescent's choice to consume alcohol for the first time and binge drink, such as peer relationships [32] and parenting styles [33]. Parental involvement is associated with decreased drinking age, but these effects may decline as age increases [34]. Sex and age impact age of consumption as males are more likely to consume at an earlier age compared to girls [14, 34]. The effects of alcohol advertisements likely changes throughout an individual's life, but children are the most susceptible. Gordon et al. [35] suggested that the impact of alcohol advertisements on children may increase after a child consumes alcohol for the first time. Adolescents who reported previously consuming an alcoholic beverage paid more attention to alcohol advertisements than adolescents who did not report prior alcohol consumption [35]. These influences, similar to alcohol advertisements exposure, were difficult to measure and not conclusively more powerful than the impact of alcohol advertisements. The choice to consume alcohol in adolescence is a myriad of influences acting in tandem.

Alcohol advertisements use the multifactorial relationship to their advantage; where as other influential factors do not or cannot join forces. Kenny, Hastings and MacKintosh [36] reported that alcohol advertisements are involved in the establishment of social norms and also use peers to potentiate the effects of alcohol advertisements on alcohol consumption. This suggests that peers contribute to the impact of advertisements and that advertisements may shape peers. Peers were often victims of the advertisement campaign and promote positive messages. It is not known whether or not parents and peers can work together to decrease the age of initiation of alcohol consumption and frequency among adolescents.

Counterarguments against the relationship between alcohol advertisements exposure and adolescent alcohol consumption are limited. Some individuals, primarily those working for the alcohol advertisement industry [37], promote that individuals will consume alcohol regardless of the presence of alcohol advertisements. According to the Drug Control Officer of Grenada, Mr. Dave Alexander, alcohol advertisements "promote brand choice" and serve as a reminder that alcohol is "present and available" rather than a form of coercion to

consume alcohol [38]. Alcohol companies agree with Dave Alexander as they claim advertisements promote brand choice, not consumption, as consumption is going to happen whether or not they advertise alcohol.

A recent study on the level of exposure to alcohol advertisements for a specific brand at a population level and the consumption of that specific brand among adolescents supported the claim that alcohol advertisements promote brand choice among adolescent consumers. The results revealed that exposure to brand specific advertisement was a predictor of consumption of that specific brand among adolescents [39]. The problem is alcohol advertisements are supposed to promote brand choice among adults, not adolescents.

Contrary to the argument that everyone will consume alcohol and will continue to consume alcohol is misleading. Data from the WHO indicates only 39% of the world's population actually consumes alcohol regularly [1]. The percentage of the population that consumes alcohol is less than 100 and varies from country to country—the highest being in Europe and lowest in Middle Eastern and North African countries. In Mali, 96% of the population abstains from alcohol consumption throughout their lifetime compared to 11% of Canadians. Although Grenada has a reputation for high alcohol consumption per capita, thirty percent of Grenadians over age fifteen report never having tried alcohol [1].

Limitations

Many biases may be embedded not only in the literature selection, but also in the literature selection of publishers. Determining the relationship between exposure to alcohol advertisements and alcohol consumption among adolescents is difficult for researchers due to the complexity of the relationship and inability to quantitatively measure the variable. Although the articles selected clarified that they accounted for confounded variables, the factors such as peer relationships and parental involvement are as challenging to measure as alcohol advertisement itself as the accuracy of the participants' reports are essential for determining the impact of the variable.

Moreover, quantitatively measuring each child's exposure to alcohol advertisements is not simple. There is not a straightforward test that tells researchers the exact amount of exposure. In spite of this limitation, studies used various techniques to measure the parameter as accurately as possible. The studies in this literature review were conducted on children who lived in areas with an elevated prevalence of alcohol consumption among youth. This study population may mask the persuasive influence of alcohol advertisements as everyone is exposed frequently.

Other limitations arise as a result of the study designs. Two types of observational studies were included in this literature review: cross-sectional and longitudinal. Limitations arise, as neither type of study is suited for this non-linear, multifactorial, problem. Both cross-sectional and longitudinal studies are inherently biased to a degree. Cross-sectional studies are often called snap-shots of situation because they involve collecting data over a very short time frame and analyzing it for correlations. The limitation of this type of study is that cross-sectional studies do not provide information about the variables before or after the point in time the data was taken; therefore, these studies are not useful for establishing causal relationships. However, each moment of a child's life is far more significant to a child than

the same moment is to an adult as children have hardly lived but a moment at all. With that in mind, the data provided through snap-shots was useful for interpreting one piece of a group of children's experiences.

Longitudinal studies are beneficial for establishing linear causal relationships and the impact of alcohol advertisements on youth is not a linear relationship. These studies examine the same group of participants over a long time frame. This involves collecting baseline and follow-up data on the variables of interest. Longitudinal studies allow researchers to examine the variable before and after exposure so to a certain degree one can estimate if overtime alcohol advertisement exposure increased and alcohol consumption by comparing baseline and follow up data of consumption with self-reported exposure to alcohol advertisements.

CONCLUSION

Correlations, associations, and other statistics do not and cannot suggest direct causation as conclusions on this topic frequently proclaim. The initiation and continued consumption of alcohol by youth is complex, yet simple. There is one factor that will influence nearly every adolescent consuming alcohol in every country and that is alcohol advertisements. Alcohol advertisements are influencing the alcohol consumption of youth and perhaps more than we can currently determine [40]. Ignoring the persuasive effects of advertisements on children in an attempt to preserve the freedom of the alcohol industry to target a vulnerable population ignores the responsibility of society to protect children. Moreover, alcohol advertisement exposure is a factor that public health interventions can effectively attempt to mediate through education and policy change.

In order to reduce alcohol consumption in youth, more than one action is necessary. The most important action is providing children with an education that enables them to think for themselves [21]. Children need to be informed that advertisements are only partially correct. They need to know that alcohol is not all fun and games rather alcohol is deadly. Regulating alcohol advertising is a common response, but may not help by itself. In the United States, the alcohol industry advertisement guidelines require 70% of the viewers be twenty-one or older. This is a voluntary compliance and is not well enforced. Therefore, it is not necessarily surprising that more alcohol advertisements target youth compared to adults and youth are being exposed more frequently [25]. In 2009 Israel implemented an alcohol policy prohibiting sales to minors and consumption in public, limiting advertising, and enforcing alcohol taxations. The policy changes combined with strict enforcement were beneficial to reducing alcohol consumption in public [41].

The United Kingdom adopted slightly more stringent guidelines as alcohol advertisements are not allowed at all during any event or television or radio programs with a primary audience less than the age of 18 years [42]. Norway and Sweden limit alcohol advertisements to the public by restricting alcohol advertisements completely on beverages containing greater than 2.5% and 3.5% of alcohol respectively [43]. The effects of these new regulations on alcohol consumption by youth may be documentable within the next decade.

The reported knowledge from the literature in this review is relevant to Grenada, West Indies. Grenada is a small island that depends on the alcohol industry to provide jobs for citizens and a source of revenue for the island. Despite popular belief that everyone in

Grenada consumes alcohol, everyone in Grenada does not consume alcohol. Similar to Europe and Australia, Grenada's adolescents are exposed to alcohol advertisements in their everyday environments and begin consuming alcohol in early adolescence. The average age is eleven [44]. According to a Drug Prevalence Survey of Grenadian secondary students [34, 44], 65% of students perceived that inhaling second hand cigarette and marijuana smoke was very harmful to your health compared to 54% of students who perceived getting drunk was very harmful to health. The fact that more students believe inhaling second-hand smoke is very harmful to health than students who believed consuming alcohol is very harmful to health suggests there may be an unbalanced understanding of the dangers of each alcohol consumption.

Government of Grenada [34], reported results from implementation of a pilot drug prevention program in pre-school and kindergarten programs during the 2007 school year. Twenty-eight Grenadian teachers attempted to complete the education program. Unfortunately, five did not receive the lesson plan manual. Teachers that did teach from the manual reported the manual as good overall, but lacked visual aids. Some teachers did not teach from the manual directly rather they taught concepts as they felt it contained information too advanced for the age group. Revision of the manual, distribution of the materials, and short training sessions for the teachers may improve the ability of teachers in Grenada to communicate the material to students and enhance the learning experience. Incorporating frequent short interactive alcohol and alcohol marketing education programs into secondary-school curriculums may be an efficient step towards increasing awareness of marketing tactics and decreasing unavoidable consequences of heavy alcohol consumption in adolescence.

ABSTRACT

The alcohol consumption levels of a nation as well as government initiatives to monitor and control it can greatly influence the health status of a population. Road traffic accidents (RTA) are caused by numerous factors that range from faulty vehicles and poor road design to driver-related, which includes alcohol-impaired driving, speeding, and driver in the distractions. However, alcohol-impaired driving is responsible for a large proportion of RTAs in the Caribbean. This paper reviews the background of alcohol related RTAs in the Caribbean and examines policy options aimed at reducing alcohol and illicit drug related RTAs in the Caribbean region.

Keywords: alcohol consumption, Caribbean, public health, road traffic accidents

INTRODUCTION

The UN General Assembly has declared 2011-2020 as the "Decade of Action for Road Safety". This is significant as road traffic accidents (RTAs) are a leading cause of morbidity and mortality in both developing and developed countries [1-4]. Annually over 1.3 million people worldwide die as a result of RTAs, and approximately 20-50 million sustain severe injuries, the majority of which require long-term treatment [5]. However, low and middle-income countries LMICs are disproportionately affected [6] where it is estimated that 94% of road traffic-related deaths occur. Though these countries have just over half of the world's registered vehicles. The burden of is higher among the youth and young adults as well as middle-aged individuals who, combined, constitute the economically most productive age groups of society [1, 3, 6, 7]. Consequently, RTA rates remains one of the most important health and social policy issues that spans all countries across all continents [5].

Understanding the risk factors associated with RTAs is as important as understanding the population at risk, for the development of policies to reduce the growing burden. Traffic incidences are multifactorial events that are caused by human factors, technical issues and environmental conditions [8], but the majority is attributed to human or driver-related factors [7]. A large proportion of RTAs are associated with driving under the influence (DUI) of either alcohol or drugs [2, 9-12]. Thus, while increased death rates in LMICs, like the Caribbean, are driven, at least in part, by rapid motorization, the lack of concomitant road safety strategy implementation and safe road infrastructure development is also largely responsible [13].

RTAs and their consequences, increased mortality and disabilities, can be reduced through preventive programs that tackle the multifactorial natures of RTAs. Such an approach would seek to address this public health concern, through a mechanism of public policies on road accident prevention and stricter enforcement of the regulations resulting from these policies. This approach recognizes that the impact of RTAs is both at the individual and the population level.

While RTAs are an issue throughout the Caribbean, this paper examined policy options aimed at reducing alcohol and illicit drug related RTAs in the Caribbean region. The specific expected outcomes are [1] improved data quality to quantify the true burden of alcohol and illicit drug related RTAs; [2] focused campaigns promoting safe driving habits; [3] increased public and governmental awareness of the realities of alcohol and illicit drug related RTAs and [4] decreased alcohol and illicit drug RTAs.

BACKGROUND

As early as 1962 the World Health Organization (WHO), through Resolution WHA27.59, challenged member states to address the urgent problem [14]. However, six and a half decades later RTAs remains a major public health concerns for countries around the globe. It is estimated that in the absence of increased efforts and new strategies and policies, the total number of road traffic deaths is expected to reach 1.9 million by the year 2020. Currently, the majority of such deaths are among vulnerable road users - pedestrians, pedal cyclists, and motorcyclists. In addition, the youth and young adults are disproportionately burdened.

It is well documented that traffic accidents are caused by numerous factors that range from faulty vehicles and poor road design to driver-related, which includes alcohol-impaired driving, speeding, and driver distraction [7, 11, 15, 16]. However, alcohol-impaired driving is responsible for the greater proportion of RTAs. Global Burden of Disease (GBD) estimates for 2010 indicated that almost 200,000 road traffic accident fatalities were the direct result of alcohol [17]. DUI of alcohol and illicit drug use presents unique challenges for public health and government officials [6]. Studies have documented that the relative risk of being involved in a RTA significantly increases at a blood alcohol content (BAC) level as low as 0.04g/dl [2, 12, 16, 18]. Movig et al. [19] provided substantial evidence that individuals involved in alcohol or substance related motored vehicle accidents have an increased risk of hospitalization.

According to the WHO's Global Status Report on road safety, raising public awareness is the first step to prevention of RTAs and is necessary to raise support for progressive legislation. In regards to alcohol consumption, such legislation may involve mandatory testing of drivers involved in RTAs, as exemplified by the Philippine Road Action Plan of 2011 [20]. It is well documented that substance use is influenced not only by individual choices, but also by a combination of social, economic, and environmental factors, and consequently a multipronged approach to raising awareness of the dangers of substance and alcohol use while driving is necessary. Such an approach should include policy changes along with educational and media campaigns as well as strict enforcement of the law [21]. Chile's experience suggests that traffic law reforms in order to have an effect on both traffic fatality and injury rates reduction require changes in police enforcement practices [15, 22]. The findings suggest that the police traffic enforcement increment registered after the introduction of its 2005 traffic law reform reduced traffic fatalities by 59% and severe injuries by 37% [15]. In addition, this case illustrated how the diffusion of successful road safety practices globally promoted by WHO and World Bank can be an important influence for enhancing national road safety practices.

CARIBBEAN REALITY

The alcohol consumption levels of a nation as well as government initiatives to monitor and control it can greatly influence the health status of a population. This paper seeks to examine English speaking Caribbean countries and the legalities of alcohol consumption in these countries.

The most populous of the countries examined is Jamaica with 2,741,000 people, followed by Trinidad at 1, 328,000. Saint Kitts and Nevis is the least populated with 52,000 people. Alcohol consumption varies from island to island, however, some themes remain consistent between them. See table 1 for a summary of the World Health Organization information regarding alcohol in the Caribbean [23].

In comparison to the rest of the English Speaking Caribbean, Antigua and Barbuda has the lowest national legal minimum age for off and on premises sales of alcohol at 10 years old. This indicates that pre-adolescent children can easily and legally access alcohol in Antigua and Barbuda. There is no set Blood Alcohol Concentration (BAC) when driving a vehicle in the nation of Antigua and Barbuda as well as in Barbados, Dominica, Grenada and

Saint Vincent and the Grenadines. The rest of the countries have a set standard of 0.08% BAC when driving a vehicle.

Despite being the country with the earliest minimum age for legal alcohol sale, Antigua and Barbuda does not have the highest Patterns of Drinking Score as of 2010. This composite measure of drinking patterns reflects how people drink instead of how much they drink, on a scale of 1 (least risky pattern of drinking) to 5 (most risky pattern of drinking). Attributes used to create this indicator include quantity of alcohol consumed per occasion, festive drinking, the proportion of drinking events when getting drunk, the proportion of drinkers who drink daily, drinking with meals, and drinking in public places [23]. On a scale of 1 to 5, with 1 being the least risky and 5 being the most risky Grenada has the highest patterns of drinking score in the English speaking Caribbean at 4.

Common to all the countries analyzed, spirits are the most consumed type of alcoholic beverage, usually almost at 50% in each country except Trinidad and Tobago. Trinidad and Tobago serves as the exception, where Beer at 54% is the main type of alcoholic beverage consumed as of WHO's survey in 2010. Trinidad and Tobago has a low Patterns of Drinking Score as of 2010 at 2, on a scale of 1 to 5, with 1 being the least risky and 5 being the most risky. Other countries, which also share the lowest Patterns of Drinking Score 2, are Bahamas, Barbados, Jamaica, Saint Kitts and Nevis and Saint Vincent and the Grenadines. Not surprisingly, these are the countries with the oldest legal minimum legal age for alcohol sales at 18 years old except Saint Vincent and the Grenadines where the legal age is 16 years.

Table 1. Summary of alcohol consumption

	AB	Bah	Bar	D	G	J	SKN	SL	SV	TT
Written national policy (adopted/revised)/National action plan	No	Yes	No	No	No	No	No	No	No	No
National legal minimum age for off-premise sales of alcoholic beverages	10	18	16	16	16	18	18	18	16	18
National legal minimum age for on-premise sales of alcoholic beverages	10	18	18	16	16	18	18	18	16	18
National maximum legal blood alcohol concentration (BAC) when driving a vehicle (general/young/ professional), in %		0.08				0.08	0.08	0.08		0.08
National Government Support for Community Action	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes

Note: AB – Antigua and Barbuda; Bah – Bahamas; Bar – Barbados; D – Dominica; G – Grenada; J – Jamaica; SKN – St. Kitts and Nevis; SL – St. Lucia; SV – St. Vincent and the Grenadines; and TT – Trinidad and Tobago.

The health consequences of alcohol consumption (morbidity and mortality) were quantified per 100,000 population (15 years and older) in 2012 in Bahamas, Barbados, Jamaica, Trinidad and Tobago only. Of these countries, Trinidad and Tobago had the highest Alcohol Attributable Fractions (AAF) for liver cirrhosis at 56.8% in males and 52.5% in females. Trinidad and Tobago also had the highest Age-standardized Death Rate (ASDR) for

road traffic accidents with males at 28.8 and Females at 13.6. The Years of Life Lost Score was 3 on a scale of 1 to 5 with 1 being the least risky and 5 being the most. These analyses were not made for most of the other countries, so it is uncertain whether Trinidad and Tobago would have ranked highest for these criteria if other countries were included.

The percentage of heavy episodic drinking was the highest in Dominica at 41.5% in males for the population and the least in Grenada at 8.0% in males for the population. In all the countries, males tended to consume alcoholic beverages more than females. In contrast, Grenada had the highest total alcohol per capita consumption in the region with males (15 years and older) at 29.9L/capita, females 19.6L/capita and both sexes 25.5L/capita.

Only Trinidad and Tobago and Bahamas have alcohol policies and interventions and a national action plan for alcohol. The rest of the examined countries all do not. Legal binding regulations on alcohol binding, placement, sponsorship and sales promotion are non-existent or limited in majority of the countries.

Within the Americas an estimated 5.4% of all deaths were attributable to alcohol consumption which is 68% higher than the world average [24]. Alcohol was responsible for approximately 10% the Disability Adjusted Life Years (DALY) lost in the Region in 2002 compared to the global figure of 4.4%. In Trinidad and Tobago, the per capita consumption per drinker in liters of pure alcohol, including unrecorded consumption, is 8.7 liters per person. Excess alcohol intake (>1-2 drinks per day) contributes an estimated 20-50% of road traffic fatalities in the region [24]. Alcohol use remains historically high in the Caribbean region [13]. Analysis of data from school surveys sponsored by Inter American Commission on Drug Abuse Control (CICAD) indicates that adolescents and youth in the Caribbean drink frequently and at an age when alcohol consumption is prohibited by law [24]. The lifetime prevalence of alcohol use among teens in the region ranged from 86.2% in Saint Lucia to 47.72% in Haiti. The mean age of first use of alcohol across the region was 11.7 years. One study noted that individuals drinking alcohol before age 15 are 5 times more likely to develop alcohol abuse or dependence than people who first used alcohol at age 21 or older. Other studies have noted that the acute consequences of underage drinking include unintentional death and injury associated with driving or engaging in other risky tasks after drinking [2, 9].

DISCUSSION

There is need for action on alcohol consumption control by English Speaking Caribbean countries. Improved alcohol consumption levels can serve to reduce mortality and morbidity, which can promote better health status for citizens and positively impacts countries. Because many countries do have an issue with alcohol and either no monitoring system or national plan, governments should develop a comprehensive road safety programme, which includes an information network and database, which will assist policy makers in addressing alcohol related RTAs more effectively. The programme should include standardized blood testing, mandatory hospital testing of all motor vehicle victims and a police officer alcohol and drug checklist.

Standardized blood testing for alcohol and other substance use in RTA should be conducted. This is to ensure comparability of data across all facilities. There is sufficiently strong evidence to indicate that having established BAC limit for drivers, supported by

standardized laboratory testing, can help reduce road traffic injuries and deaths [25-30]. A standard blood test that all hospitals use to test for alcohol and illicit drug levels in the blood of motor vehicle victims will streamline the process of collecting blood samples, remove any questions that may result from non-standardized blood samples. However, the use of blood alcohol concentration (BAC) levels, while it can, through legislation, help curb the number of RTAs, in and of itself is not enough. Successful implementation will also establish guidelines for enactment in other territories in the Caribbean. However the effectiveness of BAC levels testing is dependent on many factors aside from the availability of the test. It would require that traffic police resources be improved and further education provided to police on the general deterrence potential of BAC [31]. Its effectiveness would require heightened community education and public awareness campaigns to ensure improved knowledge of new drinking and driving regulations and how to stay within the confines of the law. The success of BAC testing is dependent on publicity and visible, rapid enforcement of BAC regulations. In addition, a decrease in trends would only be possible with support from other programmes. Alcohol misuse problems should be addressed, particularly for drunk driving offenders and repeat offenders [30].

Mandatory hospital testing should be conducted for all RTA victims. Through mandatory testing and subsequent data collection, government officials will be able to develop a more comprehensive picture of alcohol related RTAs. Improved, timely data will assist in informing policy and interventions for this major public health problem. It will also help public health practitioners to better quantify the relationship between blood toxicity (alcohol or illicit drugs) and RTAs and the proportion of the mortality and morbidity burden attributable to alcohol-related RTAs. Mandatory, routine testing will eliminate the question of whether to test or not test and make testing more objective, removing the element of subjectivity. In addition, it will remove the barrier of test results and the medical practitioner as a liaison between laboratories and the police.

The final component is police officers mandated to fill out a checklist, which includes an assessment of all individuals involved in RTAs for alcohol and drug use, at the scene of every accident that is investigated. A checklist will assist in the standardization of police protocols in quantifying the number of individuals involved in RTAs who are under the influence of alcohol or illicit drugs.

CONCLUSION

The goal of any traffic program or policy is to decrease road traffic injury, which is related to any specific issue in this case alcohol related incidences. Multicomponent programmes and policies, such as what is detailed is generally known to include a combination of efforts to limit access to alcohol or to have measures that deter alcohol use, responsible beverage consumption, sobriety checkpoints or other well-defined enforcement efforts, public education, and media advocacy all designed to gain the support of both policymakers and the general public for reducing alcohol-impaired driving and alcohol-related road traffic accidents. Studies suggest that carefully planned, well-executed multicomponent programmes that are implemented in conjunction with community

mobilization efforts are effective in reducing alcohol-related RTAs and at cost savings to the country [32].

There is need for action in the Caribbean to reduce the alcohol related mortality and morbidity of RTAs, and to establish data to support evidence or practice based decisions and programs. As data are collected policies and programs can be developed to focus educational awareness and campaigns targeting specific regions, age groups and other demographic groups that are most in need.

ABSTRACT

The purpose of this study was to assess the relationship between family structure, parental involvement and peer pressure and alcohol use among Grenadian adolescent. A secondary data analysis of the 2013 secondary school drug prevalence survey for Grenada was conducted. A nationally representative group of secondary school students were selected for the study through a two-stage sampling frame. Questionnaires were completed by students (n = 1,490) in forms 2, 4 and 5 from seventeen public and private secondary schools. The independent variables were family structure, parental involvement and peer pressure. The dependent variable was alcohol use. Continuous variables were summarized using a mean and standard deviation. Categorical variables were summarized using frequency and percent. Chi Square test A significant relationship was found between parental involvement and patterns of drinking ($X^2 = 91.9$, $p = <0.001$). Significance was also found between peer pressure and frequency of drinking. ($X^2 = 145.3$, $p = <0.001$). The findings from this study did not show any significant relationship between the different family structures and the use of alcohol among adolescents. ($X^2 = 13.78$, $p = 0.131$). A high perception of parental involvement was associated with being less likely to consume alcohol. Experiencing minimal peer pressure was associated with less use of alcohol, which was also related to strong parental involvement.

INTRODUCTION

Global alcohol consumption in 2010 was rated at 6.2 liters per person 15 years and older. In 2014, Grenada was ranked as the country with the highest rate of alcohol consumption in the Caribbean, with a rating of 12.5 liters per capita [1]. It is not known how much adolescent alcohol consumption contributed to the rating. However, the lifetime prevalence of alcohol use among secondary school students in Grenada is 72% with an average age of initiation of 12 years [2]. This high rate of alcohol use during adolescence is a cause for concern specifically from a public health, economic and social perspective. Excessive use of alcohol can have health and social burdens on communities. Social and cultural factors such as peer pressure, family structure and parental involvement are major contributing factors to adolescent alcohol use in Grenada.

Adolescence is characterized as a time of experimentation. This age group is usually more vulnerable to alcohol-related harm because their brain is still developing [3]. Therefore, early introduction of alcohol, before age 14, is related to an increased risk of alcohol addiction and misuse, which can continue throughout an individual's lifetime [4]. Alcohol dependence and abuse can result in impaired health status, alcohol-related motor vehicle crashes and other unintentional injuries [4]. Thus, it is important to understand the factors associated with early adolescence alcohol consumption.

At the adolescent stage children go through physical, emotional, intellectual and social change. Although the consequences of alcohol use have been studied, the social and cultural factors underlying their early initiation of drinking is less understood [4]. Understanding the role socio-cultural factors play in adolescent alcohol consumption would help develop effective school and community based programs and alcohol policies directed towards adolescents. This can reduce the burden adolescent alcohol use place on communities thus improving the health and social well-being of these communities which is an important aspect of public health.

Alcohol has accounted for 3.3 million or 5.9% of all deaths worldwide [4]. Although the majority of deaths and disabilities are among adults, the use of alcohol is common during adolescence. Approximately 10.4 million adolescents between twelve and twenty years consumed more than "just a few sips" of liquor in 2009 [5]. Additionally, children drink more as they get older, 70% of adolescents consume at least one drink by age fifteen [5]. Research examining adolescent alcohol use patterns predicted that by age 16, a significant percentage of teenagers were consuming alcohol at levels considered harmful for adults. Furthermore Heron et al. found that early exposure to alcohol was strongly linked to its use later on in life [6]. Similarly, a report on Alcohol in Europe stated approximately all 15-16 year-old students (>90%) consumed alcohol during their life. On average, they began to drink at 12½ years, and got drunk for the first time at 14 years [7]. Possible predictors to adolescent alcohol use by age 15 were early parental drinking and heavy drinking by the father. Additionally, adolescents belonging to two-parent households were less intense alcohol users compared to those from single-parent households [8].

When observing adolescent drinking practices, attention should be paid to the direct social context in which they drink and how their patterns are structured based on differences

created within society [9]. Adolescent drinking patterns should be understood at the same level at which their practice is guided such as symbolic significances discussed through societal communications. Young people are “cultural agents” who construe their traditional values and meanings to create their own individual social worlds [9]. The way adolescents construct their social world is crucial in understanding their drinking habits.

Historically, the Caribbean has been a key producer of sugar cane and rum. Hence it is habitual for adults to drink alcohol in social gatherings since it is a part of their regular diet [10]. Although knowledge of adolescent health status in the Caribbean is limited, separate information on alcohol abuse indicated a cause for concern [11].

Previous studies suggested 49 to 67% of youths consumed alcohol during their lifetime [12]. Similarly, a Caribbean drug use survey found that previous year’s prevalence of 55.16% was distinct in ages 14 or less and 15-16 [10]. From age thirteen, adolescents are more susceptible to experiment with minor misbehavior since they are strengthening their identities [10]. Therefore higher incidence of alcohol use can be attributed to adolescent experimentation.

Prinstein, Boergers and Spirito, conducted a study on adolescents and their friends reported an adolescent’s health risk behavior was strongly determined by their association with friends who engage in risky behavior [13]. Thus, use of alcohol by peers was linked to use of alcohol by adolescents themselves. On the contrary, it was highlighted that adolescents who associated with non-deviant peers were likely to abstain from alcohol use [13]. Furthermore, assessment of adolescent vulnerability to peer influence utilized the social learning theory. For a behavior to be reinforced, adolescent’s observation of their peer’s behavior does not have to occur. Believing that peers approves of a certain behavior can encourage the behavior. Therefore, the perception that peers would approve of adolescents alcohol use may be the influential factor in early adolescent when direct pressure is not present [14].

Peer influence was also examined in relation to other variables such as parenting style, parental monitoring and family structure. Low levels of authoritative parenting and monitoring can increase the influence that peers have on adolescents [13]. Therefore, high peer influence along with high family dysfunction were linked to increased health risk behavior.

Family dysfunction was also directly associated with increased alcohol use. Research examining risk factors for adolescent substance use highlighted that adolescents in dysfunctional families turn to alcohol as a stress reliever if there was no family support [15]. Parental monitoring of adolescents behavior was not effective in these families due to poor communication. On the other hand, general communication, relationship between parent and child, parental involvement and parental monitoring were found to be predictors of delayed alcohol initiation and reduced levels of future drinking by adolescents [16]. It was emphasized that although parental monitoring is necessary it is not sufficient to influence adolescent’s behavior [17].

Although the various studies were consistent with the variables to be explored in this study, insufficient research has been done to examine their relationship to adolescent alcohol use in Grenada. A study on substance abuse among young people in Grenada stated that although there is quantitative statistics on substance abuse among young people, inadequate qualitative research has been done on the subject [18]. The social disorganization of society was seen as the major influencing factor for alcohol use. As stated by Douglas, the problem of

alcohol use and abuse is a social construction of the society we live [18]. Recommendation was made by the Drug Avoidance Secretariat to conduct a study to identify new findings to reduce the incidence of substance abuse among young people. Based on the preceding studies, and the gap in knowledge, it is important to continue the study of socio-cultural factors associated with adolescent alcohol use in Grenada.

Therefore, the purpose of this study was to assess the relationship between family structure, parental involvement and peer pressure and alcohol use among Grenadian adolescent. Results from the study would be used to make recommendations to a school-based program tailored towards delaying the initiation of adolescent alcohol use.

METHODS

The data for this study was retrieved from the 2013 secondary school drug prevalence survey inclusive of Grenada and Carriacou. An anonymous, self-administered questionnaire developed by the Drug Control Secretariat of Grenada and the Inter-American Drug Abuse Control Commission (CICAD) was used for the survey. This questionnaire contained 105 questions representing drug use, parental involvement, consequences of drugs and health risk behavior. For the purpose of this study, 36 questions were used. The items measured family structure, parental involvement, peer pressure and alcohol use.

The following describes the methods used to obtain the sample used in the drug prevalence survey. A random sample of 1,490 students in forms 2, 4 and 5 from seventeen public and private secondary school students throughout the island of Grenada and Carriacou were selected for this survey. A two-stage sampling frame was used to select the participants. The first stage randomly sampled the secondary schools. Sixteen schools were randomly selected from twenty secondary schools on the island of Grenada. To ensure representation of Carriacou and Petite Martinique, one secondary school was randomly selected from Carriacou. The second stage included a random selection of classrooms in forms 2, 4 and 5 within each of the selected secondary schools. All students ($n = 1,860$) in the selected classrooms were asked to participate. A total of 1,460 students participated, representing an 80% response rate. The demographic characteristics of the students are provided in Table 1.

The independent variables in this study were family structure, parental involvement and peer pressure. The dependent variable was alcohol use. The following describes the measurement of each variable.

Family Structure was defined as the composition of the adult figure (s) in the household. The family structures were two [2] parents, one [1] parent, and guardian/relative. When there when no mother, father, stepfather, stepmother, grandparent or guardian/ relative identified, then a sibling is used. When there is no sibling, a girlfriend or boyfriend is used. This represented the no parent family structure.

Seven questions were used to measure the perceived parental involvement of the students. They included:

1. Parent's expectation to be told of student's whereabouts
2. Parents control of the time students come in at nights
3. Level of attention parents pay to students activities at school

4. How often students had meals together with their parents
5. Parents knowledge of students close friends
6. Parents knowledge of TV shows watched
7. Parents knowledge of students whereabouts

Table 1. Student demographics

Demographic indicator	(%)
Type of school	
Public	97.1
Private	2.9
Age (in years)	
11-14	31.2
15-16	41.5
17+	16.8
Gender	
Female	51.3
Male	48.3
Form in school	
2 nd	37.5
4 th	35.5
5 th	27

For the purpose of analysis, parental involvement was rated using the following scale of 1-7. Minimally involved (less than or equal to 2), moderately involved [3-5], very involved [6-7].

Peer Pressure was defined as how much influence the student's friends had over their actions, specifically drinking habits.

Alcohol use was defined as the patterns in which the students consume alcohol. The following scale was used to classify the different patterns of drinking among the students: Non-drinker-never consumed alcohol. Infrequent drinker-consumed one or two alcoholic drinks a few times during the month. Weekend drinker-consumed alcohol only on weekends. Chronic drinker-consumed alcohol daily or several days of the week. Adolescence was defined as the period in human development that occurs between childhood and adulthood, from 10 to 19 years [1].

Data Analysis

The data from the survey was entered into Excel twice to ensure there was no risk of data entry errors. In order to tabulate the data, the final excel spreadsheet with the data was converted to SPSS format version 19.

Continuous variables were summarized using a mean and standard deviation. Categorical variables were summarized using frequency and percent. All analyses used a level of significance of 0.05.

To determine differences in drinking patterns by family structures chi-square tests were conducted. Chi-square tests were conducted between each parental involvement variable and drinking pattern. Chi-square tests were also conducted to determine differences in drinking patterns based on peer pressure.

RESULTS

Approximately forty percent (40%) of students belonged to two parent households whereas households with one parent, guardian/other relative and no parents were six [6], eight [8] and eight [8] percent respectively (refer to Figure 1). The majority of students (26%) were categorized as infrequent drinkers. Approximately eighteen (18%) percent of students were categorized as non-drinkers, 13.4% of students were categorized as weekend drinkers and 12.1% were categorized as chronic drinkers (refer to Figure 2).

Table 2. Summary of family structure and students patterns of drinking

Family structure	n	Non drinker N (%)	Infrequent drinker N (%)	Weekend drinker N (%)	Chronic drinker N (%)
Two parent	265	67 (25.3)	101 (38.1)	48 (18.1)	49 (18.5)
One parent	3035	819 (27)	1103 (36.3)	585 (19.3)	528 (17.4)
Guardian/relative	362	87 (24)	141 (39)	78 (21.5)	56 (15.5)
No parent	167	27 (16.2)	66 (39.5)	37 (22.2)	37 (22.2)

Note: $X^2 = 13.8$, $p = 0.13$.

Note: Thirty seven percent (37%) percent of students did not disclose their family structure.

Figure 1. Family structure of students.

There was no significant difference among the percentages for patterns of drinking in two parent, one parent and guardian/relative households. Students in a no parent household (22%) were more likely to consume alcohol. Overall, there was no significant relationship between the different family structures and patterns of drinking among the students, $p = 0.13$. Therefore, a difference in family structure is not likely to have an impact on a student’s drinking patterns (refer to Table 2).

Students who perceived their parents to be very involved in their lives were less likely to consume alcohol. With the perception of minimal parental involvement, the percentage of students in the category of non-drinker decreased by 17%. Therefore, students who perceived

their parents to be minimally involved in their lives were more likely to consumed alcohol. This was represented by a six (6%) increase in students who were weekend and chronic drinker. There was no significant difference in drinking patterns among students who perceived their parent to be very involved or moderately involved in their lives. Represented by p values <0.05, significant results were found at all levels of parental involvement. Generally, there was a significant relationship between parental involvement and students patterns of drinking. Thus the level of parental involvement is likely to influence a student's alcohol use (refer to Table 3).

Note: Thirty one percent (31%) of students did not disclose their drinking patterns.

Figure 2. Summary of students' patterns of drinking.

Table 3. Summary of student's perception of parental involvement and patterns of drinking

Parental involvement (category)	n	Non drinker N (%)	Infrequent drinker N (%)	Weekend drinker N (%)	Chronic drinker N (%)
Very involved (6-7)	923	329 (35.6)	300 (32.5)	142 (15.4)	152 (16.5)
Moderately involved (3-5)	2057	500 (24.3)	821 (39.9)	404 (19.6)	332 (16.1)
Minimally involved (<3)	852	162 (19.0)	298 (35)	202 (23.7)	190 (22.3)

Note: $X^2 = 91.9$, $p < 0.001$.

Table 4. Summary of Peer pressure experienced and patterns of drinking

Peer pressure to drink	n	Non drinker N (%)	Infrequent drinker N (%)	Weekend drinker N (%)	Chronic drinker N (%)
Yes	2157	408 (18.9)	499 (37.7)	499 (23.1)	46 (20.2)
None - minimal	1635	570 (34.9)	593 (36.3)	242 (14.8)	230 (14.1)

Note: $X^2 = 145.3$, $p < 0.001$.

Students who experienced peer pressure were more likely to consume alcohol represented by an eight [8] and six [6] percent increase in weekend and chronic drinkers respectively. Students who experienced minimal peer pressure were less likely to consume alcohol

represented by approximately thirty five (35%) who were nondrinkers or infrequent drinkers. A significant relationship was found between the two spectrums of peer pressure and student’s patterns of drinking supported by p values less than 0.05. Results suggest that peer pressure is likely to have an effect on a student’s drinking patterns (refer to Table 4).

Table 5. Summary of parental involvement in relation to peer pressure experienced to drink alcohol

Peer Pressure to drink alcohol	n	Minimally involved (<=2) N (%)	Moderately involved (3-5) n (%)	Very involved (6-7) N (%)
Yes	2817	638 (22.6)	1587 (56.3)	592 (21)
None-minimal	2619	248 (13.3)	1389 (53)	882 (33.7)

Note: $\chi^2 = 148.5$, $p < 0.001$.

There was no significant difference between students who experienced peer pressure and perceived their parents to be minimally involved (23%) and very involved (21%) in their lives respectively. Students who perceived their parents to be very involved in their lives were less likely to experience peer pressure. This was represented by a twenty (21%) percent increase in students who perceived their parents to be very involved (34%) compared to those who perceived their parents to be minimally involved (13%) within the category of minimal peer pressure. The two spectrums of peer pressure yielded significant values as it relates to different levels of parental involvement. Therefore, the level of parental involvement can influence whether a student experiences peer pressure (refer to Table 5).

DISCUSSION

We examined the impact of family structure, parental involvement and peer pressure on adolescent alcohol consumption patterns. We did not find any significant relationships between family structure and patterns of alcohol use, which is inconsistent with the findings of other studies. However, associations were found between parental involvement and consumption patterns, with lower perceived involvement being associated with increased consumption. In addition, we found consistent evidence that peer pressure impacts alcohol use. Furthermore, parental involvement had a linear relationship with peer pressure with greater involvement resulting in less peer pressure.

No significant relationship between family structures and the pattern of alcohol consumption among adolescents were found. However, Podana et al. [7], found that adolescents from a single parent household use alcohol more intensely than adolescents from two-parent households. Additionally, Vanassche et al. [18] also found that adolescents living in single parent or step- families had a higher likelihood of being frequent drinkers than their counterparts from intact families. It is possible that the results of this study differ due to alcohol use being a social norm in Caribbean countries where alcohol consumption is an important part of cultural and social activities. As such differing parental structures may not significantly impact adolescent drinking habits. Nevertheless, consistent with a study by Soyibo and Lee [20], the prevalence of alcohol use among adolescents was found to be greater than 50%.

The students' perception of parental involvement had a significant effect on their pattern of drinking. Students who perceived their parents to be very involved in their lives did not consume as much alcohol as the students who perceived their parents to be minimally involved in their lives. This may be due to the practice of authoritative parenting styles, which is demonstrated to be associated with lower levels of alcohol use among adolescents [2]. A positive emotional attachment between parent and child, as well as acceptable levels of openness and control distinguishes this style of parenting from other styles. As such it serves as a protective factor against high risk behaviors such as alcohol use. The opposite is true for parents who practice more liberal styles of parenting. A student's perception of parental involvement may differ from the parent's perception; therefore, the results in the study related to parental involvement can be skewed.

Similar to the findings of a study by Nash et al. [22], results showed that students who experienced little or no peer pressure were less likely to binge drink or consume alcohol overall. The majority of students who experienced peer pressure were categorized as weekend or chronic drinkers. In relation to peer pressure and parental involvement, students who perceived their parents to be very involved in their lives experienced little or no peer pressure. The strong interpersonal relationship between parent and adolescent may act as a buffer against peer pressure. Prinstein et al. [13] also found that low levels of parental involvement could result in increased peer pressure experienced by adolescents thus leading to alcohol consumption. These results further support the notion that peer pressure is not the only factor that contributes to adolescent alcohol use.

The present study indicates that parental involvement through monitoring of activities in and out of school, knowing who their friends are, spending time together and having control of the time they return home at nights can act as protective factors against early alcohol use. Therefore, interventions aimed at delaying the initiation of alcohol use among adolescents should also target parents. Additionally, findings suggest that student's perception of their parents can influence their patterns of drinking. The inclusion of various aspects of parental involvement such as educational support, constructive parenting and efficient discipline into school-based alcohol prevention programs has been found to be successful [21]. Moreover, a variety of parenting strategies for reducing adolescent alcohol use can be tailored for use in this setting [16].

RECOMMENDATIONS

To curb the issue of increased alcohol consumption among the Grenadian population, the National Alcohol Policy should be revised to include a minimum drinking age. While this measure alone cannot reduce the incidence of alcohol use specifically among adolescents, the findings from this study suggest more emphasis needs to be placed on helping adolescents develop healthier relationships with their parents and peers. This in turn can assist in their decision making as it relates to their alcohol usage.

The Health and Family Life Education (HFLE) program is one of the few programs adolescents are exposed to within the school system that attempt to address issues related to family life, social life and alcohol use within one curriculum. These aspects are included under the theme of Self and Interpersonal relationship. Therefore it is a suitable existing

program to which recommendations can be made based on the variables examined in this study and the results obtained. However, the effectiveness of this program is frequently questioned especially as it relates to delaying the initiation of alcohol use among adolescents.

While the regional evaluation of HFLE in 2009 did not find a constant pattern of positive effects on the health outcomes of students [23], these findings support the importance of programs like Health and Family Life Education in the school systems throughout the Caribbean. Improving its effectiveness may help adolescents obtain the necessary skills to foster positive family and social relationships. This can contribute to decreased incidence of alcohol use among adolescents in Grenada.

Chapter 5

ALCOHOL MISUSE IN ADULthood FOLLOWING EXPERIENCES OF PSYCHOLOGICAL MALTREATMENT DURING CHILDHOOD

***Samantha Longman-Mills*, PhD
and Carole Mitchell, PhD***

Department of Community Health and Psychiatry,
Faculty of Medical Sciences,
University of the West Indies, Mona Campus, Jamaica

ABSTRACT

This study seeks to identify whether exposure to psychological maltreatment in childhood is predictive of alcohol misuse, in adulthood, among Jamaican university students. Systematic sampling techniques were utilized to gather data on 382 university students. Measures utilized were the Kessler Psychological Distress Scale (K10), the Adverse Childhood Experiences questionnaire, and CICAD drug use questions. Alcohol misuse was reported by 12.6% of the students, while 66.7% reported exposure to psychological maltreatment. Logistic regression analysis identified psychological maltreatment as being predictive of alcohol misuse (OR = 2.701; 95% CI 1.22 - 5.97; $p < .01$) as well as higher levels of psychological distress (OR = 1.988; 95% CI 1.211-3.265; $p < .01$) among select university students. Public health policies aimed at reducing psychological maltreatment may result in the reduction of alcohol misuse.

Keywords: alcohol misuse, child abuse, psychological maltreatment, substance misuse

INTRODUCTION

‘Alcohol misuse’ refers to the excessive consumption of alcohol, which is a known risk factor for road accidents, injuries, risky sexual behaviours, violence, and the development of chronic illnesses such as liver cirrhosis, hypertension and heart disease [1]. A national survey had identified alcohol as being the most widely consumed psychoactive substance in Jamaica, with 39% of the adult population reporting alcohol consumption within the past month [2]. It was also noted that 6.9% of Jamaicans are alcohol misusers, consuming 60 grams or more of alcohol on one occasion, within the past month [3]. Furthermore, one of every five Jamaican road accident fatalities was found to be attributable to alcohol misuse [3]. As a result, alcohol misuse is a key public health concern in Jamaica and therefore it is essential to understand its drivers.

Within developed nations, exposure to psychological maltreatment during childhood has been implicated as a risk factor for alcohol misuse in adulthood [4, 5]. Psychological maltreatment consists of both emotional abuse and emotional neglect, therefore consisting of all cognitive and affective forms of maltreatment [5]. Emotional abuse includes restriction of movement as well as non-physical acts that emotionally damages a child such as threatening, exploiting, belittling or terrorizing a child [6]. While emotional neglect involves not providing for a child’s emotional need for love, support and belonging [6].

Psychological maltreatment is the least reported type of maltreatment [7] even though it is believed to be the most frequently occurring form, as it tends to accompany all other types of abuses [8]. Its low reporting frequency may be attributable to the difficulty in providing evidence that substantiates this type of maltreatment, as well as the cultural belief that ‘words’ do not have any longstanding negative impact. As such, within a Jamaican context, humiliating, threatening, demeaning and rejecting a child is widespread and is often seen as a viable, effective and less severe form of disciplining technique than spanking; and therefore is reserved for everyday offences [9, 10]. Consequently, many persons who have experienced this type of disciplining are often not aware that it constitutes or meets the criteria of maltreatment [11].

It has been postulated that exposure to psychological maltreatment may bring about psychological distress and thereby increase the likelihood of alcohol misuse [6]. Persons experiencing psychological distress are believed to be at an increased risk of psychoactive substance misuse, as they may try to alleviate their distress by self-medicating with psychoactive substances [12]. It has also been hypothesized that the type of psychoactive substance that is selected is associated with the nature of the distress; with alcohol misuse facilitating an emotional numbing, when faced with overwhelming negative emotions [12]. Therefore, alcohol may be the chosen drug subsequent to psychological maltreatment experiences.

The significant adverse outcomes associated with alcohol misuse, makes it necessary to explore the psychological maltreatment-alcohol misuse link. However, only scant research has been conducted in this area, within a Jamaican context. The goal of this exploratory research is to investigate the predictive relationship between exposure to psychological maltreatment and later alcohol misuse, within a Jamaican context; among a population that is expected to have an elevated frequency of alcohol misuse, university students.

METHODS

The data for this study were part of a larger multi-country research in Latin America and the Caribbean to investigate the relationship between adverse childhood experiences and psychoactive substance use. This segment of that research employed systematic sampling techniques within a cross-sectional survey design to gather information on 382 students from a select university in Jamaica. The measures utilized are the Emotional Abuse and Emotional Neglect scales from the Adverse Childhood Experiences questionnaire (ACE) (Centers for Disease Control and Prevention 2012), the Kessler Psychological Distress Scale (K10) [13] and substance use questions from the Inter-American Drug Abuse Control Commission (CICAD) Drug Use questionnaire.

Adverse Childhood Experiences Questionnaire

The Adverse Childhood Experiences Questionnaire (ACE) assesses the impact of exposure to childhood maltreatment and household dysfunction on development of public health issues. The ACE questionnaire is widely used by the Centers for Disease Control and Prevention and has been found to display adequate reliability and validity [14] in a variety of cultural settings. The emotional abuse scale of the ACE consists of two items: 'Did a parent or other adult in the household: 1) Often or very often swear at, insult, or put you down? 2) Often or very often act in a way that made you afraid that you would be physically hurt?' The potential response choices were 'almost never or never,' 'some of the time,' 'half of the time,' 'most of the time' and 'almost always or always.' An affirmative response to any question indicates the presence of emotional abuse and also gives a measure of the perceived frequency of the emotional abuse. The ACE Emotional Neglect Scale consists of five items originally derived from the Childhood Trauma Questionnaire [15]. The emotional neglect items assess the failure of a guardian to provide love, support, encouragement, and belongingness. These items are known to demonstrate good reliability and validity among university students [16].

Kessler Psychological Distress Scale

The Kessler Psychological Distress scale (K10) was initially developed to screen for the presence of non-specific psychological distress among the United States populace [13, 17, 18]. However, its concise nature and cross-cultural validity has resulted in the K10 and its abbreviated version, K6, being translated into numerous languages and being widely used by the World Health Organization. The 10 items of the K10 assess for anxiety and depressive symptoms that are commonly identified in many psychological disorders [19]. Therefore, high scores on this scale indicate an increased likelihood of being diagnosed with a psychological disorder [20, 21].

CICAD Drug Use Questionnaire

The Inter-American Drug Abuse Control Commission (CICAD) Drug Use Questionnaire has been translated into several languages and is widely used within Latin America and the Caribbean. Select questions were taken from this questionnaire to provide a measure of alcohol use and misuse in accordance with the DSM-V definition. These questions provided a measure of alcohol consumption frequency as well as a measure of the negative outcomes that occurred as a result of alcohol misuse.

Procedure

The research questionnaire was pretested among university students to ensure that they were being interpreted as intended. Using a table of random numbers, university faculties were randomly selected and every third student within the vicinity of the faculty office was invited to participate. Power analysis identified the minimum required sample size to be 311, when using a sampling error of 5%.

The data entry process involved the use of the double entry method to reduce the possibility of errors. Data analysis was performed using the Statistical Package for the Social Sciences (SPSS) version 19. Univariate and bivariate statistics were employed to explore the relationship between alcohol misuse and exposure to psychological maltreatment in childhood.

RESULTS

Three hundred and eighty two students (279 females and 103 males) participated in this segment of the study. The mean age for the sample was 21.27 years ($SD = 4.389$) with 88.5% being young adults between the ages 18-24 years. The demographic and psychosocial characteristics of the sample are summarized in Table 1. A majority of the students reported being raised in middle class socioeconomic backgrounds. The most frequently used psychoactive substance was alcohol, with alcohol use within the past month being reported by 24.2% of the sample (19.5% of the females and 36.9% of the males). Twenty one percent (21.1%) of alcohol users reported consuming alcohol weekly, 11.4% reported a frequency of 2 or 3 days/ week, while 3.2% reported a frequency of 4 days or more each week. Alcohol misuse was reported by 12.6 % of the sample (9% of the females and 20% of males). Of note, 14.4% of the students reported that they lived with an alcoholic in their household. Psychological maltreatment was reported by 66.7 %, with exposure to emotional abuse being reported by 64.7% of the students. Half of the students (52.8%) who had experienced psychological maltreatment were not aware that their experiences had met the criteria for maltreatment.

The students' level of psychological distress was assessed and the results are displayed in Table 2. One third of the students (33.1%) reported moderate to severe levels of psychological distress, with an equivalent percentage of females and males reporting increased levels of psychological distress.

Table 1. Demographic and psychosocial characteristics of the sample

Characteristics	Total	
	(f)	(%)
Gender		
Female	279	73
Male	103	27
Age (years)

Cocaine	3	0.8
Heroin	3	0.8
Ecstasy	3	0.8
Inhalants	5	1.3
Unprescribed use of prescription drugs	7	1.9

Table 2. Levels of psychological distress by gender

Level of Distress	Males		Females		Total	
	(f)	(%)	(f)	(%)	(f)	(%)
Minimal - Mild	67	67	179	66.8	246	66.8
Moderate - Severe	33	33	89	33.2	122	33.2

Table 3. Dysfunctional outcomes associated with alcohol misuse

Dysfunctional Outcomes	Alcohol Misuse	
	f (%)	p value
Repeatedly absent from classes	6 (1.6)	.008
Had unprotected sexual activity	17 (4.5)	.000
Had unintended sexual relations	12 (3.2)	.000
Family conflicts	7 (1.8)	.003
Had partner conflicts	17 (4.5)	.000
Financial difficulty	16 (4.2)	.000
Health problems	4 (1.1)	.019
Fighting resulting in arrest	2 (.5)	.140
Fines for driving under the influence	2 (.5)	.140
Motor vehicle accidents	3 (.8)	.150
Have been incarcerated	2 (.5)	.140
Legal problems	5 (1.3)	.004
Academic problems	11(2.9)	.000

Students who reported consuming alcohol with there being associated adverse outcomes were assessed to provide a measure of alcohol misuse. Table 3 outlines the frequency of alcohol misuse and the associated dysfunctional outcome. The most frequently identified dysfunctional outcomes occurring due to excessive alcohol consumption were unprotected sexual activity (4.5%) and experiencing partner conflicts (4.5%).

The relationship between alcohol use and psychological distress was investigated using the Chi-square statistic. A non-significant relationship was found between experiencing psychological distress and consuming alcohol ($p > 0.05$). However, a logistic regression examination of the relationship between experiencing psychological distress and alcohol misuse was found to be significant ($X^2 = 10.051$, $df = 1$, $N = 368$, $p = 0.002$). Students reporting increased levels of psychological distress were 2.76 times more likely to misuse alcohol (OR = 2.76; 95% CI 1.48 - 5.17). Additionally, exposure to psychological maltreatment was found to be predictive of experiencing higher levels of psychological distress ($X^2 = 7.774$, $df = 1$, $N = 364$, $p = 0.005$) (OR = 1.988; 95% CI 1.211 -3.265). Logistic regression analysis was also conducted to investigate whether or not there is a predictive relationship between exposure to psychological maltreatment during childhood and alcohol misuse in adulthood. A significant predictive relationship was identified ($X^2 = 7.109$, $df = 1$, $N = 378$, $p = 0.008$) (OR = 2.701; 95% CI 1.222 - 5.970). Therefore, students who had experienced psychological maltreatment had an increased likelihood of excessive alcohol consumption by a factor of 2.701.

DISCUSSION

Excessive alcohol consumption is a global phenomenon with grave public health implications for any nation. In accordance with international and local research, this study identified alcohol consumption as the psychoactive substance of choice for university students [22-24]. This preference for alcohol consumption may be attributable to its relatively low cost, easy accessibility as well as the misperception that its use is associated with minimal risks. Mirroring the results of several international studies, a greater percentage of males than females reported alcohol consumption [23, 25, 26]. Alcohol consumption being greater among males, may be attributed to a variety of reasons including a more positive attitude towards alcohol consumption and its associated outcomes, less refusal skills when with drinking peers, as well as the ease of accessibility [25].

Interestingly, most of the students were from a middle socioeconomic background and as seen in previous research, individuals from a higher socioeconomic status are more likely to misuse alcohol. Previous research has also revealed that “heavy episodic drinking” increased with higher SES [27].

Two-thirds of the students experienced psychological maltreatment (66.7%) but half of these students were unaware (52.8%) that their experiences had constituted a form of mistreatment. This lack of awareness highlights the cultural acceptance of verbal assaults as a practical and less severe disciplining technique in Jamaica. Nonetheless, this exploratory study found that experiencing psychological maltreatment during childhood almost tripled (OR = 2.701; 95% CI 1.222-5.970) the probability of alcohol misuse among select Jamaican university students. Furthermore, students who were exposed to psychological maltreatment

were more likely to have elevated levels of psychological distress, which may be indicative of a psychological disorder [17]. Therefore, this perceived innocuous disciplining technique has longstanding implications for individual mental health as well as public health.

Consistent with international studies, exposure to psychological maltreatment was predictive of alcohol misuse in adulthood [28-30]. This psychological maltreatment- alcohol misuse link may occur due to the need to cope or to self-medicate for the negative emotions arising from the psychological maltreatment experiences [30]. Therefore, alcohol misuse may occur to facilitate the numbing of negative emotions.

As anticipated, alcohol use did not exhibit a significant relationship with psychological distress ($p > 0.05$). This non-significant relationship was expected as alcohol consumption in Jamaica is culturally endorsed for a wide variety of significant events, such as weddings and funerals, as well as non-events. Therefore, identifying a specific pattern of alcohol consumption would be unlikely. On the other hand, experiencing psychological distress was found to almost triple the odds ($OR = 2.76$; 95% CI 1.48-5.17) that alcohol misuse would occur. This finding that psychological distress increases the likelihood of alcohol misuse further supports the self-medication hypothesis.

Of note, an equivalent percentage of males as well as females (33%) were found to be experiencing psychological distress, however a greater percentage of males (20%) misused alcohol than females (9%). These findings may indicate that excessive alcohol consumption may be the preferred method to deal with emotional difficulties among males, while females may utilize other methods. Additionally, it highlights that the psychological maltreatment - alcohol misuse link is not an automatic one. Being exposed to psychological maltreatment does not automatically bring about alcohol misuse as the level of psychological distress being experienced as well as other mitigating factors, are expected to have an influence.

CONCLUSION

This research has identified that among select Jamaican university students, psychological maltreatment is predictive of higher levels of psychological distress and also an increase probability of alcohol misuse. This finding reveals another target area for the creation of public health policies aimed at reducing excessive alcohol consumption. As by eliminating psychological maltreatment, a reduction in alcohol misuse may occur. However, this exploratory study should be interpreted with caution as the data collected was self-report in nature, and therefore the possibility exists that some participants may have responded in a socially desirable manner. Additionally, psychological maltreatment frequently accompanies other forms of maltreatment and on those occasions, it may not be possible to accurately measure the impact of each form of maltreatment.

ABSTRACT

This study sought to determine the overall prevalence of suicidal behaviours and differences related to gender and alcohol use among a nationally representative sample of Jamaican secondary school adolescents. A cross-sectional survey design was used to gather information on suicidal behaviour and substance use in a sample of 3,471 students island-wide, using a self-administered questionnaire comprised of the Suicidal Behaviours Questionnaire-Revised (SBQ-R) and another standardized questionnaire. Suicide risk prevalence was 19.85%. There were no significant direct associations between alcohol use and suicidal behaviour ($p > 0.05$ in all cases). However females who used alcohol had higher suicide risk scores, more reports of lifetime suicidal ideation, past year ideation and lifetime suicide attempt than males who used alcohol ($p < 0.05$ in all cases). Females who used alcohol had higher means for past year suicide ideation and suicide risk scores than females who did not use alcohol ($p < 0.01$). There were no significant differences between male alcohol users and non-users and suicidal behaviour ($p > 0.05$). Suicide prevention measures for Jamaican adolescents should take gender differences and alcohol use into consideration when developing programmes or interventions to address these behaviours.

Keywords: suicidal behaviour, substance use, adolescents, Jamaican

INTRODUCTION

Suicide is a complex, multi-causal public health issue and remains a leading cause of death with an estimated annual global burden of 800,000 suicide deaths [1] and a mortality rate of 16.7 per 100,000 which is projected to increase [2, 3]. Suicide behaviours exist on a continuum, ranging from suicide ideation to suicide plans, suicide attempts and completed suicide [4].

Nock et al. [5] pellucidly define suicide ideation as “thoughts of engaging in behavior intended to end one’s life and a suicide plan as “the formulation of a specific method through which one intends to die.” A suicide attempt is the “engagement in non-fatal but potentially self-injurious behavior for which there is evidence (either implicit or explicit) that the person intended at some (non-zero) level to kill himself/herself” [5, 6] whereas suicide may be defined as, “death caused by self-directed injurious behavior with any intent to die as a result of the behavior” [7].

The problem of suicidal behaviour is of great relevance among adolescents, with increased risk among adolescent females [8]. In the 15-19 year old age group it is ranked the fourth most common cause of death globally among boys, and the third for girls [9]. Overall, the mean suicide rate of 7.4 per 100,000 in this age group [9].

However, Abel et al. [10] concluded that the suicide rate in Jamaica is relatively low with a mean overall incidence of 2.1 per 100,000. In another 12-month prevalence of suicide ideation in a subset of Jamaican adolescents, 10-15 years old, was found to be 9.7% [11], and among school-children from grades 6, 9 and 11 surveyed in 1996, 11% reported attempting suicide at least once [12].

Among the main predisposing factors among adolescents are gender, alcohol and other substance use [8, 13]. Other factors identified in the literature include, prior suicide attempts, unstable family systems, family history of suicide attempt, low socioeconomic status and impulsive traits.

Gender is a major predisposing factor for suicidal behaviour [5]. Research indicates that adolescent females are two to three times more likely to attempt suicide than adolescent males, but males are five times more likely to complete suicide [8]. Adolescent females also have higher rates of suicidal ideation [13].

Additionally, alcohol has been found to account for the increase in suicide mortality among adolescents who express suicidal behaviour [14-16], with up to 63% of all persons completing suicide had substance use disorders, mostly alcohol [17]. The frequency of alcohol among adolescents is more predictive of suicide attempt than suicide ideation [8, 18] possibly due to the fact that alcohol use accelerates the transition from ideation to suicide attempt. In adolescent females, severity of depression predicted suicidal ideation, and alcohol consumption predicted severity of suicidal behaviour [19].

The present study was aimed at exploring the prevalence of suicidal behaviours among a cluster of secondary school adolescents and determining whether there were associations between suicidal behaviour, gender and alcohol use.

METHODS

This was a cross-sectional survey design consisting of 3, 471 participants were selected from a sample of public and private secondary schools in Jamaica which were stratified. The cluster sampling procedure was carried out in two stages, using the automated C-Survey program. Firstly, 38 school clusters were generated with the probability of selection proportional to size. Secondly, a grade was then selected from each stratum to represent key developmental periods that are typically investigated in health related, school based adolescent research [20]. This sampling technique resulted in the selection of the 2nd, 4th and 6th forms. However, as the number of students in the 6th form in Jamaica is comparatively low [21], both grades in the upper grade level were included in this study. All participants completed two self-administered questionnaires:

- A standardized questionnaire developed by the Inter-American Uniform Drug Use Data System (SIDUC) [22].
- The Suicidal Behaviors Questionnaire-Revised (SBQ-R).

The standardized SIDUC questionnaire has previously been used with secondary school students in Jamaica. It consists of items on socio-demographic, school performance and substance use.

The Suicidal Behaviors Questionnaire-Revised (SBQ-R) is a 4-item scale, developed by Osman et al. [23], that is available in the public domain. The SBQ-R is brief, with a completion time of approximately 5 minutes, and assesses lifetime suicidal behaviours, past year frequency of suicide ideation, and the likelihood of a future suicide attempt. The total score ranges from 3-18 points, with higher scores indicating higher suicide risk. This instrument has been previously standardized among secondary school students with Cronbach's alpha of 0.87 [23].

Approval to conduct this study was granted by the school principals, the Ministry of Education and the Ministry of Health. The Ethics Committee of the University of the West Indies, Mona, also granted ethical approval. Written informed consent was obtained from the parents or guardians of the students and the students themselves completed assent forms. Participants were provided with a list of mental health professionals, whom they could contact in the event that they felt distress during the process.

Statistical Analysis

Data were entered and cleaned in the Statistical Package for the Social Sciences (SPSS) version 17. Statistics were performed to produce frequencies for sociodemographic variables as well as to calculate the prevalence of the following dependent variables; suicide risk, ideation, attempt and plan. Independent variables included alcohol use, gender, geographical location, school factors, family factors and aggressive behaviour traits. Independent sample t-tests, and Chi Square analyses were used to explore gender differences in suicidal behaviour. Pearson's Correlation analysis was used to explore relationships between alcohol use and suicide risk scores.

RESULTS

The sample consisted of 3,289 participants, 41.2% male and 58.8% females. The response rate was 87.7%. The age of students ranged from 11-19 years, with a mean age of 14.97 years ($SD = 1.7$). The vast majority of students attended public (97.8%), co-educational schools (83%). The spread across a grade levels was as follows; 8th grade- 31%, 10th grade- 32.1%, 11th grade-26.5% and 12th grade-10.3%. The urban (50.6%) and rural (49.4%) representation were equivalent.

Scores on the suicide risk prevalence (SBQ-R Scale) revealed; suicide risk at 19.8%, lifetime suicide ideation was 35.6%, among those who expressed lifetime suicidal ideation, 70.2% reported past year suicide ideation. Additionally, 15.8% had a suicide plan, 6.1% suicide attempt, 27.4% suicide threats and 8.4% indicated a future intention to attempt.

Gender and Suicidal Behavior

Independent samples T test revealed that there was no significant difference between males and females for suicidal risk, ($t(1115) = -1.788$, $p = 0.074$). However, Table 1 shows that more females than males reported both lifetime ($t(903.5) = -3.013$, $p = 0.003$) and past year suicidal ideation ($t(311.8) = -2.438$, $p = 0.015$). Similarly more females reported lifetime suicidal attempts and suicidal threats. There was no statistically significant differences between gender and suicidal plan ($p > 0.05$).

Additionally Chi-square analysis revealed significant differences between gender and threatening suicide, with more reports of threatening suicide coming from females (%) than from males (%) ($X^2 = 18.44$, $N = 2951$, $p < 0.01$).

Alcohol Use and Suicidal Behavior

Most students admitted to using alcohol in their lifetime (56.7%). The past year use was 35.9% and 18% reported drinking in the last 30 days. However Pearson's Correlation analysis revealed no significant associations between alcohol use (lifetime, past year, or last 30 days) and suicidal behaviour (ideation, plan or attempt, $p > 0.05$).

Table 1. T-test and descriptive statistics for suicidal ideation and attempt by gender

	Sex						95% CI for Mean Difference	t	df	p value
	Male			Female						
	M	SD	n	M	SD	n				
Lifetime (ever) suicidal ideation	0.322	0.468	1147	0.38	0.486	1719	(-.093, -.022)	-3.164	2518.2	0.002*
Past year suicidal ideation	0.67	0.471	476	0.72	0.447	805	(-.106, -.002)	-2.023	956.46	0.043**

Key: * $p < 0.01$, ** $p < 0.05$.

Gender Differences in Suicidal Behaviour among Alcohol Users

The data was split based on lifetime use of alcohol. Independent Sample t-test analysis on gender differences in suicidal behaviour among alcohol users revealed that females who used alcohol had higher suicide risk scores (SBQ-R scale) than males who used alcohol (see Table 2). Compared to males who used alcohol, more females who used alcohol also reported lifetime suicidal ideation, past year ideation, lifetime suicide attempt and were more likely to have a suicide plan ($p < 0.01$).

Table 3 shows that there were no significant differences between male alcohol users and non-users and suicidal behaviour ($p > 0.05$ in all cases).

When female alcohol users were compared to non-alcohol users analysis revealed that there were significant differences between female alcohol users and non-users and total suicide risk score as well as past year suicide ideation with female alcohol users displaying higher means than non-users (see Table 4).

Independent sample T-test analysis was also performed within gender, to explore differences between males who use alcohol and suicidal behaviour compared with males who do not use alcohol and their suicidal behaviours.

Table 2. T-test and descriptive statistics for suicidal ideation and attempt by gender among alcohol users

	Sex						95% CI for Mean Difference	t	df	p value
	Male			Female						
	M	SD	n	M	SD	n

Suicide risk score	7.66	3.775	163	8.51	3.948	421	(-1.552, -0.139)	-2.35	582	0.019**

Key: * $p < 0.01$, ** $p < 0.05$.

Additionally, cases were selected to reflect only those who reported lifetime alcohol use and suicidal behaviour ($n = 864$). Independent samples T test analyses were performed to explore associations between gender, sociodemographic, school and family factors and marijuana use. These analyses revealed that significantly more females ($M = 0.836$, $SD \pm 0.371$) than males ($M = 0.683$, $SD \pm 0.466$) reported lifetime marijuana ($t(285) = -4.072$, $p < 0.001$). Furthermore, significant more males ($M = 0.691$, $SD = 0.463$) than females ($M = 0.533$, $SD = 0.499$) who reported lifetime alcohol use and suicidal behaviours lived in urban communities ($t(346) = 4.047$, $p < 0.001$). Also significantly more males ($M = 0.54$, $SD = 0.50$) than females ($M = 0.32$, $SD = 0.466$) who reported lifetime alcohol use and suicidal behaviours lived in violence prone communities. However there were significant gender differences among those who reported alcohol use and suicidal behaviour and variables such as school type, school factors, relationship with parents, living arrangements and aggressive behavioural traits ($p > 0.05$ in all cases).

DISCUSSION

In this study 19.85% of secondary school students surveyed were found to be at risk for suicide based on their total scores on the SBQ-R scale. For specific suicidal behaviours; they reported suicidal ideation (35.5%), suicidal plan (15.8%), suicidal attempts (6%) reported. The estimated prevalence of suicidal behaviours in adolescents vary widely in the literature, not only because of socio-cultural differences but also because of inconsistencies in the operational definitions of suicidal behaviours.

The findings in this study, for suicidal ideation (35.6%) is consistent with what is reported widely in the literature, a meta-analysis of 128 international studies of both community and school-based adolescents reported a mean lifetime prevalence of 29.9% [24]. With regard to the lifetime prevalence of suicide attempts in adolescents, the result from this study (6.0%) is also consistent with cross-national figures which range from 1.5% to 12.1% [25].

GENDER AND SUICIDAL BEHAVIOR

Consistent with the literature [8, 26] this study found the rates of suicide ideation, plans and attempts were higher in females than in males. Numerous research studies have proposed explanations for this gender difference in suicidal behaviour. One proposed explanation is that gender roles may dictate the individual's response to psychological distress [27]. The idealized 'hyper-masculinity' [28] of the Jamaican male includes a cultural assumption that outward displays of emotionality are feminine. This may result in the channelling of psychological distress into more gender-acceptable forms including anger, antisocial behaviour and violence [27].

Furthermore, the wish to conform to this hyper-masculine ideal may also result in a conscious or unconscious denial of emotional distress. That is, males may consciously refuse to admit to suicidal behaviours for fear of appearing 'weak'. Alternatively, they may not have been socialized to develop an 'emotional language' to either recognize or appropriately communicate these feelings.

Alcohol Use and Suicidal Behavior

The majority of the participants in this study reported lifetime alcohol use 56.7%. While past year and one month alcohol use were reported at 35.9% and 18% respectively. There were no direction associations noted between alcohol use and suicidal behaviour in this study. These findings fail to support research finding that substance use is linked to adolescent suicidal behaviour [5, 29, 30].

However Sher [31] in his commentary article on alcohol consumption and suicide pointed out the relationship between alcohol use and suicide is not conclusive as it varies across countries. For example, Portugal which has the highest rate of alcohol consumption in Europe but has a relatively low rate of suicide and shows a negative relationship between alcohol consumption and suicide while this is not so for other countries in Europe such as France, Russia and Finland [31]. These differences were attributed to levels of alcohol consumption where alcohol use disorders and binge drinking practices were noted to contribute more suicidal behaviours than merely using alcohol. These aspects of alcohol use were not explored in the present study and would be important to investigate in future studies.

Gender, Alcohol Use and Suicidal Behavior

Interestingly, when alcohol use was explored with gender and suicidal behaviour distinct differences were noted. Females who used alcohol had higher suicide risk scores than males who used alcohol. There were no differences noted between male alcohol users and male alcohol non-users and suicidal behaviours. However, female alcohol users showed higher means for past year suicidal ideation and suicide risk scores than female alcohol non-users.

Additionally, significantly more females than males who used alcohol and reported suicidal behaviour also reported lifetime (ever use) use of marijuana. Light et al. [32] suggested that self-medication with substances is a mechanism used to cope with adverse life events. Also both substance use and suicidal behaviour may also be mediated by stressful life

experiences [33]. Consequently, future research among adolescents particularly females, should seek to explore the presence of stressful life experiences as a possible contributing risk factor for substance use and suicidal behaviour.

Noteworthy is the finding that more males than females who reported alcohol use and suicidal behaviour lived in urban communities and violence prone areas. Exposure to violence and aggressive behaviour especially during childhood are known to contribute to suicidal behaviours [34]. Exposure to violence may propel males to the use of alcohol which also contributes to impulsivity associated with suicidal behaviour. Here again further research is needed to explore this relationship among male adolescents.

CONCLUSION

This study was limited by the use of a cross-sectional design and the possibility of recall bias. The inability to concurrently assess and control for the presence of mood, psychotic and externalizing disorders was also a limitation, as these disorders have strong associations with suicide. Nonetheless, calculations of the contingency coefficient allowed for statistical quantification of the contribution of each of several independent variables to suicidal behaviour outcomes. Additionally, given that suicidal behavior is the result of a complex interaction of numerous biological, psychological and social variables, there were other factors such as personality traits, mental disorders, childhood trauma, familial psychopathology and exposure to suicide in the social environment that would have been worthy of investigation.

Nevertheless this study is important as it highlighted the relationship between gender, alcohol use and suicidal behaviour. These findings should be used to guide gender specific approaches to suicide prevention among Jamaican adolescents.

ACKNOWLEDGMENTS

The authors of this study wish to express appreciation to the United Nations Children's Fund (UNICEF) for funding this suicide research through the Ministry of Health's Mental Health Unit. We thank the Mental Health Unit's team for their support in the development and administration of this research project. Also, we wish to thank the Inter-American Drug Abuse Control Commission (CICAD) for allowing this study to utilize items from its SIDUC survey. The authors also give a special thanks to the National Council on Drug Abuse for allowing the suicide data to be collected in conjunction with the National Drug Prevalence Secondary School Survey.

ABSTRACT

Alcohol is the most commonly used and abused psychoactive substance among adolescents and young adults in Jamaica. Several studies suggest that parental factors play significant roles in both the initiation and continuation of alcohol use among adolescents. This present cross-sectional study conducted by the National Council on Drug Abuse (NCDA) with technical support and funding by the Organization of American States' Inter-American Drug Abuse Commission (CICAD) sought to examine the association between parental involvement, parents' alcohol use and parent-adolescent relationship and adolescent alcohol use in Jamaica. The sample consisted of 3,365 secondary school students ages 13, 15 and 17 years drawn from 38 schools using a stratified random sampling method. The Inter-American Uniform Drug Use System (SIDUC), the standardised Questionnaire for Secondary Schools, a self-administered instrument, comprising 99 items was used to capture socio-demographic, parenting influences, drug use and other psychosocial data. Spearman's Rho and Pearson's statistics were performed on key variables based on the objectives outlined for this study. Results show adolescent alcohol use decreases as parental involvement increases; that

* Corresponding Author's Email: eulaleemathompson@gmail.com.

adolescent alcohol use increases as parents' drinking habits increase and that as relationship with mother or father improves, adolescent alcohol use decreases. These results were significant ($p < 0.01$). The findings highlight the importance of parent training and public education on possible links between parental influences and adolescent alcohol use.

Keywords: parental influences, parents' drinking habit, adolescent alcohol use, Jamaica

INTRODUCTION

Adolescence spans the period from the dependence of childhood to the independence of adulthood [1]. It is the developmental phase commonly characterised by turbulence as adolescents attempt to negotiate Erikson's psychosocial challenge of identity versus role confusion [2, 3]. Experimentation with identity roles is not unusual during this critical developmental phase and substance use is one of the ways that teenagers engage in the risk taking which is typical of adolescence [4].

Drinking is among a constellation of high-risk behaviours engaged in by adolescents. Alcohol is the most commonly used and abused psychoactive substance among adolescents and young adults in Jamaica [5]. About 66% of students surveyed ($n = 4,536$) in Jamaica admitted to using alcohol compared to 22.2% admitting to cigarette use, 21.5% marijuana and 25.5% inhalants [5]. Some surveys indicate the age of first use for alcohol is 11.71 years, while others have found that most adolescents who drank in the last year (37%) admit to 14 to 15 years old as their initiation ages [5, 6]. The Jamaican adolescents' preferred alcoholic beverage is beers or stouts, 70.8%, followed by premix alcoholic coolers 56.5%, wine, 32.8% and liquor, 32.6% [6]. When preferred alcoholic beverages are disaggregated by gender, it was found that the premix alcoholic coolers were preferred by more adolescent females (72%) than males (44.9%) and beers or stouts were preferred by more adolescent males (84.6%) than females (52.2%) [6].

A review of the pattern of alcohol use among Jamaican youth indicates that lifetime prevalence is about 66%; past year prevalence is about 48% and past month prevalence is 34% [5]. Lifetime prevalence in other Caribbean states are also comparatively high, for example, in Antigua and Barbuda (71%); Barbados (76%); Guyana (61%) and Trinidad and Tobago (82%) [6].

Highest alcohol prevalence among youth by age group, in Jamaica, was in the 15 to 16 age group (55%) compared to 52% in the 17 and over age group and 36% in the 14 and under age group [5]. In terms of adolescent alcohol use by gender, lifetime prevalence for males was nearly 70% compared to 62% for females; past year prevalence was 52% males and 42% females; past month prevalence was 36% males and 30% females [5].

Alcohol use is a major public health concern [7]. An association has been made between adolescent use of alcohol or illicit drugs and increased risk for poor school performance, and vice versa [8]. Also, intoxicated adolescents, through impaired judgement, are more likely to engage in risky sexual encounters and create situations where unsuspecting members of the public, friends and family members can be harmed in vehicular accidents or in violent behaviours [7, 9]. These risky behaviours associated with hazardous alcohol consumption facilitate increased psychological, financial and economic burden in increased medical costs,

loss of workplace productivity, greater impact on the criminal justice system and emotional strain on family members and friends [7, 9].

Parental Influences

It is commonly assumed that peer factors play a more important role than parental influences in adolescent alcohol use [10]. However, several studies suggest that parental influences do in fact, play a significant role in both the initiation and continuation of alcohol use among adolescents [10]. The parental influences of interest in this study are parental involvement, parents' alcohol use and parent-adolescent relationship.

Parental Involvement

Parental involvement as defined in this study includes issues of parental monitoring and parental behaviour management of adolescents. Parental monitoring describes parents' awareness of and communication of concern about their child's or children's activities [10]. This parental factor has been linked with adolescent alcohol and substance use in various cross-sectional and longitudinal studies [11-15]. High levels of parental monitoring are associated with lower adolescent alcohol use and lower levels of parental monitoring have been consistently associated with higher levels of adolescent alcohol use, externalising behaviours, sexual risk-taking and internalising behaviours such as low self-esteem, maladjustment and poor academic achievement [10].

Parents' Alcohol Use

Research has found that parents' use of alcohol increases the likelihood that adolescents would also consume alcohol [16] and further, an extensive body of evidence indicates that parents' substance use is predictive of adolescent substance use [17-19]. Higher levels of alcohol use have also been found among adolescents whose parents are dependent on alcohol when compared with adolescents with non-dependent parents [20]; paternal, but not maternal, alcohol use has been found to have a direct effect on the alcohol use among adolescent boys [21] and maternal alcohol use, more so than paternal alcohol use, has been found in the literature to be related to adolescent psychopathology such as depression, conduct disorder and alcohol dependence [22].

Other family-related factors, laws and cultural norms have also been shown to be associated with adolescent alcohol use. Various studies have identified parents' norms, attitudes, and beliefs on the issue of adolescent alcohol as significant influences on adolescent alcohol [23, 24]. An Australian study of 650 teenage participants found that adolescents are less likely to drink if their parents show disapproval of adolescent drinking but, adolescents are likely to engage in more drinking when parents convey tolerance and permissiveness to drinking [25].

Parent-Adolescent Relationship

Parent-adolescent relationship quality underpins many aspects of parenting and is an ongoing interplay between parents and adolescents, affecting and being affected by other parenting factors such as parental monitoring and parenting style. Adolescents' perception of their relationships with their parents as warm and supportive has been associated with lower levels of adolescent alcohol use and lower rates of problematic use and misuse [10, 26]. A study with a sample of 493 adolescents who misused alcohol found that the participants were significantly more likely to report lower parental care [27]. Parent-adolescent relationship quality also mediated the effect of temperament on alcohol misuse among males with good parent-adolescent relationships reducing the contribution of temperament to alcohol misuse. However, the mediating effect was different among females as it was found that relationship quality and temperament separately predicted alcohol use, and good parent-adolescent relationship quality did not minimise the effect of temperament on alcohol use [28].

The aim of the present study is to examine the relationship between the dependent variable, adolescent alcohol use, and three independent variables, parental involvement, parents' alcohol use and parent-adolescent relationship.

METHODS

The present study was cross-sectional and conducted by the National Council on Drug Abuse (NCDA) in collaboration with the Organisation of American States' Inter-American Drug Abuse Commission (CICAD); the latter provided technical support and funding for this project. This was part of a regional project being conducted in Jamaica and 12 other Caribbean islands.

Sample

The target population included all public and private secondary schools in Jamaica. A randomly selected sample frame was used with school lists being provided by the Ministry of Education and the Private School Association of Jamaica. Thirty-eight schools were selected representing a target sample of 3,949 students at the lower, middle and upper levels of the school system representing ages 13, 15 and 17 years.

Instrument

The Inter- American Uniform Drug Use System (SIDUC), the standardised questionnaire for secondary schools was used in this study. This was a self-administered questionnaire comprised of 99 items which captured information related to socio-demographic characteristics, parental involvement, parental drug use, relationship with parents and other relevant information.

Procedure

Approval to undertake the study was granted through the Ministry of Health and Ministry of Education. Informed consent and assent forms were distributed to the identified schools by the NCDA prior to data collection. Trained researchers administered the questionnaires to students who returned the informed consent and assent forms. Students were assured of confidentiality and anonymity and reminded not to include any identifiable information on the questionnaire. They were also provided with a list of mental health professionals associated with the project although minimum harm was expected through their participation.

Data Entry and Analysis

The data were entered into a pre-constructed Microsoft Excel database constructed by OAS/CICAD. The data was cleaned using the double data entry technique. Individual school files were merged and exported to the Statistical Package for the Social Sciences (SPSS). Spearman's Rho and Pearson's statistics were performed on key variables.

RESULTS

This section presents the results of the study. First, descriptive statistics regarding the demographic variables are presented and then the results relating to dependent variable, adolescent alcohol use, by the independent variables parental involvement, parents' alcohol use and parent-adolescent relationship.

Descriptive Statistics

There were 3365 students who participated in the study, 42.7% were males and 57.3% were females. Most participants reported that they lived with their mother (75.1%), a significant number also lived with their brother(s)/sister(s) (47.9%), and father (37.3%). The lifetime prevalence of alcohol use was 64.1% while one year use was 44% and one month use, 33.6%.

Parental Involvement and Alcohol Use

Parental involvement was measured by the several questions (See Table 1) over lifetime, past year and one month periods. The Spearman's Rho and Pearson's were conducted to examine the association between parental involvement and adolescent alcohol use. Table 1 indicates that overall there were weak negative associations with parental involvement and adolescent alcohol lifetime, past year and one month use ($p < 0.01$). This indicates that as parental involvement increases, adolescent alcohol use decreases. Except in the case of 'how well do parents know friends' and student alcohol use in the past month ($r = -0.05$, $p > 0.05$) which was not significant.

Parents' Alcohol Use

Parents' alcohol use was measured by the several questions (See Table 2) over lifetime, past year and one month periods. The Spearman's Rho and Pearson's were conducted to examine the association between parents' alcohol use and adolescent alcohol use. Table 2 indicates significant weak positive associations between mother/guardian and father/guardian drinking habits and student alcohol use over lifetime, past year and one month use in all cases ($p < 0.01$ and $p < 0.05$). This indicates that as parental drinking habits increase, adolescent alcohol use increases. It also indicates that parents (mother/father/guardian) reaction if adolescents are caught drunk or tipsy was significantly associated with student alcohol use over lifetime, one year and one month. It was a weak negative relationship indicating that whereas parents' reaction became less negative, students' reports of alcohol use increases ($p < 0.01$).

Parent-Adolescent Relationship

Parent-adolescent relationship was measured by two questions (See Table 3) over lifetime, past year and one month periods. The Spearman's Rho was conducted to examine the association between parent-adolescent relationship and adolescent alcohol use. Table 3 shows that relationship with parents (mother, father or guardian) had a weak negative association with adolescent alcohol use over lifetime, last year and one month. These associations were significant at the $p < 0.01$ level except in the case of relationship with father/guardian and last 30 days use which was not statistically significant ($p > 0.05$). This result indicates that as relation with mother or father improves, student alcohol use decreases.

Table 1. Parental involvement by adolescent alcohol use

Parental Involvement	Alcohol Use by Adolescent		
	Ever used	Last 12 months Use	Last 30 days use
<i>Parents knowledge where student is</i>			
correlation co-efficient-Spearman rho	-0.109	-0.800	-0.114

p value	0.000**	0.012**	0.220

** p significant at $p < 0.01$ level.

Summary

Results show adolescent alcohol use decreases as parental involvement increases; that adolescent alcohol use increases as parents' drinking habits increase and that as relations with mother or father improves, adolescent alcohol use decreases. These results were significant ($p < 0.01$).

DISCUSSION

In this study, we found that overall as parental involvement increases, adolescent alcohol use decreases ($p < 0.01$). This finding is consistent with the literature that generally indicates that parents who show greater awareness of their adolescent's activities and openly communicate their concern about their adolescent's activities, which may include monitoring television shows watched, school work, friends, and schedule, tend to report lower adolescent alcohol use [11-15]. The converse of low parental monitoring of adolescent activities has been associated, both in cross-sectional and longitudinal studies, with increased adolescent alcohol use [10]. Seemingly simple but nurturing activities such as parents and adolescents

having dinner together and parents paying attention to their adolescents' homework have consistently been shown to amount to large pay-offs not only in reducing adolescent alcohol use but also in managing other high-risk behaviours that characterise the turbulence of this developmental [2, 3, 29]. The reality, based on the literature, is that parenting behaviours that are responsive to the needs of children and adolescents and which exude nurturance and monitoring continue to play influential roles in late adolescent alcohol use, and other high-risk behaviours, even when placed against formidable peer influences such as alcohol offers, social modelling and perceived norms [23].

To a large extent, parental involvement in their adolescents' lives is mediated by the adopted parenting style which includes methods of adolescent behaviour control and disciplining. Baumrind [30] isolated three main parenting styles – authoritarian, authoritative and permissive – based on variations in control or monitoring and warmth or nurturance exhibited by parents towards their children and adolescents. The authoritative parenting style that is high on warmth, rational, flexible, though firm and clear about expectations with limited use of punitive disciplinary practices when compared to authoritative parenting styles has been credited with producing more well-adjusted adolescents [30, 31]. In fact, the protective effect of authoritative parenting style against adolescent alcohol and other substance use has been well established in the literature [29].

Parents' Alcohol Use

We found that as parental drinking habits increase adolescent alcohol use increases over lifetime, past year and 30-day periods ($p < 0.001$ and $p < 0.05$). This positive association between these two variables is consistent with other findings in the literature. While this present study was cross-sectional in design and carries limitations in terms of making cause-and-effect statements, there is an extensive body of evidence making parental alcohol use and dependency predictive of adolescent alcohol use [17, 18, 19]. The study by Zhang et al. [21] has found that in relations to male adolescent drinking, it is paternal alcohol use rather than maternal drinking that plays the crucial link between the variables. This association could quite possibly be explained in behaviour modeling by boys of the same sex parent, particularly as they move into adolescence and are clarifying issues of identity formation [32]. However, while the boys may be modelling paternal behaviour, maternal drinking is not without its pitfalls as it has been associated, far more than paternal drinking, with adolescent psychopathology such as alcohol dependence, depression and conduct disorder [22]. This differential in adolescent outcome between paternal and maternal drinking could be the subject of further studies in a Jamaican and Caribbean population.

It was also found that parents' attitude towards alcohol use was negatively associated with adolescent alcohol use with less negative reaction by parents being associated with increased adolescent alcohol use. It could be argued that parents' attitudes, norms and beliefs underpin their own alcohol use and it is therefore not surprising that various studies in the literature have reported similar negative association [23, 24].

Parent-Adolescent Relationship

In this study, it was found that as relationship with mother or father improves, adolescent alcohol use decreases ($p < 0.01$), except in the case of relationship with father and last 30-day use which was not statistically significant ($p > 0.05$). This finding is consistent with those reported by several researchers [10, 26, 27]. The relationship between parents and adolescents, as previously discussed, is largely mediated by parenting style adopted. Authoritative parenting, which is high in nurturance and control, has been found to be protective against adolescent drinking and other substance use that authoritative parenting style protects adolescents against drinking and smoking while parenting styles that were more inflexible and administered more punitive disciplinary methods were associated with more substance dependency in adolescent [31].

CONCLUSION

In conclusion, the findings indicate that adolescent alcohol use decreases as parental involvement increases; that adolescent alcohol use increases as parents' drinking habits increase and that as relations with mother or father improves, adolescent alcohol use decreases. These findings were significant ($p < 0.01$) and consistent with the findings of other studies in the literature. The findings highlight the importance of parent training and public education on possible links between parental influences and adolescent alcohol use.

ACKNOWLEDGMENTS

The authors wish to thank the National Council on Drug Abuse for allowing access to their data for the publication as well as the Inter-American Drug Abuse Control Commission for providing the funding for the broader research conducted on drug prevalence among Secondary school students in Jamaica. The research on which we report met legal and ethical standards, and was approved by the relevant institutional review board.

ABSTRACT

Much of the research on the public health implications of alcohol consumption focuses on high-wealth nations in the Americas and Europe, alcohol is a problem in many developing countries. However, there are a proportion of alcoholic beverages that are illegally produced and considerably unregulated. Much of the alcohol consumption in Grenada comes from illegally distilled rum, colloquially called babash or bush rum. The public health complications of babash consumption is currently an un-researched public health issue. *Methods:* Bottles of locally and illegally produced babash were collected from three different regions in Grenada. Three of the bottles were randomly selected to be analyzed for toxicological impurities by the Grenada Bureau of Standards and St Louis Testing Laboratories. *Results:* Methanol analysis performed determined that while the ethanol concentrations varied between samples, the methanol concentrations of all three samples were well below both the maximum tolerable concentration (MTC; 2.0%). Heavy metal analysis tested for 32 different analytes and determined elevated levels of aluminum, calcium, chromium, copper, sulfur, silicon, and zinc. *Recommendations:* Based on this chemical analysis, there is sufficient evidence to suggest that babash, beyond the effects of ethanol, may pose a public health risk to consumers. Although none of the samples reached the hazardous or toxic limits found in the human body, they can

* Corresponding Author's Email: chyounger@ghc2.com.

still have acute and chronic effects on the body depending on the consumption rates and chemical content.

Keywords: alcohol consumption, Grenadian Bureaus of Standards (GBS), illegal distillation, public health, heavy metal poisoning, babash, bush rum, methanol toxicity, ethanol

INTRODUCTION

Many nations have severe problems with alcohol abuse and over-consumption, and the morbidity and mortality associated with alcohol is well researched [1, 2]. Alcohol use is therefore the subject of much interest for public health interventions. The global burden of alcohol is difficult to determine, because there are many facets involved, which include healthcare costs, criminal justice costs and collateral damage from accidents. Current estimates suggest that 3-8% of global deaths and 4-6% of global disability-adjusted life-years (DALYs) are attributable to alcohol consumption [2]. In economic terms, a 2011 study estimated the 2006 cost of alcohol in the United States to be \$223.5 billion, most of which was due to lost productivity and specifically attributable to binge-drinking; this enormous sum averages to approximately \$1.90 per alcoholic drink consumed [3]. While much of the research on the public health implications of alcohol consumption focuses on high-wealth nations in the Americas and Europe, alcohol is a problem in many developing countries.

Grenada, for example, is the largest consumer of alcohol per capita in the western hemisphere, and many other countries in the Caribbean region are just as high [4], yet there is a noticeable void in the public health research on alcohol in the Caribbean region. Specifically, in Grenada, alcohol abuse is a large concern for the Ministry of Health (MoH) and the MoH has been investigating interventions to help reduce the burden of alcohol abuse in Grenada [5]. Emergency department (ED) studies found that in the Caribbean and Latin American Regions alcohol consumption has an extremely high prevalence among injured prevalence in the ED, and ED doctors in Grenada report that the ED is full of alcohol-related injuries and co-morbidities [6, 7].

The production of most alcohol consumed worldwide is subject to regulation by government authorities [8]; however, there are a proportion of alcoholic beverages that are illegally produced and considerably unregulated. According to the World Health Organization (WHO) an estimated 24.8% of alcohol consumed worldwide was unrecorded [4]. Part of the problem is that small batch distilleries have become extremely popular over the past decade in the creation of low volume, personalized craft liquors [9, 10].

Much of the alcohol consumption in Grenada comes from illegally distilled rum, colloquially called babash or bush rum [6, 11]. Babash provides a cheap, strong source of alcohol for many and is strongly tied to the culture of Grenada, as many social events will feature babash in some amount [6, 12].

In Grenada babash is typically produced in stills using copper pots or iron pots for the boiling process, bamboo, cut fire hoses and copper for tubing, and plastic barrels for cooling [11]. The production of babash takes place in the “bush” – a heavily wooded area- that is well hidden. Because of the less than sanitary conditions of production and bottling, and no standard formula, babash can have different levels of ethanol, methanol, arsenic, copper, lead, zinc and other contaminant levels. Because there is no regulatory oversight, it is difficult to

assess the toxicological safety. Potentially exposing consumers to highly toxic levels of substances such as lead, methanol, and pure ethanol leading to subsequent adverse health effects [13]. Raising public health concerns of consumption of possible contaminants. Illegal spirits have been found to have high levels of methanol [14] and lead [15], suggesting acute and chronic toxicities from consumption.

The consumption of illegally produced alcohol is by no means a new occurrence, as there has been much research into consumption of moonshine in the United States [16, 17] and other countries [4], however, there is an absence of research on babash in the Caribbean region. This is potentially troubling, as unregulated alcohol, such as babash, is estimated to account for 30% or more of total alcohol consumed worldwide [18].

The public health complications of babash consumption are currently un-researched public health issues. Two major public health concerns are: (1) the direct physical effects of consumption, which include methanol-, ethanol-, and heavy metal poisoning; and (2) the social and cultural significance of babash in Grenada, which not only includes how babash is viewed by Grenadian communities, but babash's importance to its producers, merchants, and consumers. The social and cultural significance is crucial to help plan and develop any potential interventions and will help predict barriers to success.

The goal of this study was to assess if babash should be treated as a public health issue, or, if it is simply a cheaper means of alcohol for consumers. Specifically, the aims of this study were to assess the quality of babash and determine the potential health effects of consumption.

METHODS

Seven bottles of locally and illegally produced babash were collected from three different regions in Grenada (Grenville, Vincennes, and Beaton). Three of the bottles were randomly selected to be analyzed for toxicological impurities by the Grenada Bureau of Standards and St. Louis Testing Laboratories. The Grenada Bureau of Standards (GBS) completed a chemical analysis, reporting on the alcohol impurities and level of ethanol and methanol content for each sample. St. Louis Laboratories conducted a full metal analysis on each sample for the 33 of the most commonly sampled metals.

RESULTS

Methanol Analysis performed by the Grenadian Bureaus of Standards (GBS) determined that while the ethanol concentrations varied between samples, the methanol concentrations of all three samples were well below both the maximum tolerable concentration (MTC; 2.0%) and EU general limit for consumption (0.40%) (See Table 1). In the analyzed contents from sample 1, the level of ethanol was 85% and contained a higher level of methanol and ethyl acetate than what is safe to consume. There were other impurities whose concentrations were not significant enough to pose a threat to public health. The other two samples had above 40% ethanol and also contained constituents similar to those found in the sample 1.

Table 1. Methanol and ethanol content

Sample	Volume (mL)	pH	Brix (%)	Ethanol (%)	Methanol (%)	Methanol (ppm)
Standard (Pure EtOH)	-	6.95	19	-	0	-
#1	750	5.22	18.8	85.6	0.1	100000
#2	750	4.96	15.9	43	0.003	3000
#3	750	4.46	15.3	48.4	0.02	20000
Methylated Spirits	-	-	-	95	5.0	5000000

Table 2. Volatile impurities analysis

Sample	Impurities
1	Acetaldehyde, Methanol, Ethyl-Acetate, <i>N</i> -Propanol, <i>Sec</i> -Butanol
2	Methanol, Ethyl-Acetate, <i>N</i> -Propanol, <i>Sec</i> -Butanol
3	Acetaldehyde, Methanol, Ethyl-Acetate, <i>N</i> -Propanol, <i>Sec</i> -Butanol, Acetone, Isobutanol, Active Amyl Alcohol, Isoamyl Alcohol, <i>N</i> - Amylalcohol

Table 3. Alcohol metal analysis (in mg/L)

ANALYTE (mg/dl)	#1	#2	#3	MCL
Silver	<.0.05	<.0.05	<.0.05	0.1
Aluminum	1.13	28.7	0.31	0.02
Arsenic	<.0.05	<.0.05	<.0.05	0.01
Boron	<.0.05	<.0.05	<.0.05	2.4
Barium	<.0.05	<.0.05	<.0.05	2
Beryllium	<.0.05	<.0.05	<.0.05	0.004
Cadmium	<.0.05	<.0.05	<.0.05	0.005
Chromium	0.13	0.27	0.14	.1
Copper	12.2	4.98	18.5	1.3
Iron	0.15	0.69	0.54	0.015
Zinc	0.05	0.22	10.6	11

MCL Maximum contaminant level from the United States Environmental Agency.

Volatile impurity analysis was also performed by GBS using GC-Chromatography, but, due to a lack of an internal standard, the analysis was only qualitative. The volatile impurity analysis identified 9 unique compounds between the three samples are presented in Table 2. Because the quantity of the impurities of the compounds could not be determined, no health effects can be estimated, however the presence of the impurities is definitely still worth as they are carcinogenic.

Heavy metal analysis performed by St. Louis Testing Laboratories tested for 32 different analytes and determined elevated levels of aluminum, calcium, chromium, copper, sulfur, silicon, and zinc (Table 3). Of these analyzed, the levels of aluminum, copper, arsenic and chromium are of most concern. Heavy metal analysis of 32 different contaminants elucidated dangerously elevated levels of copper (>10X MCL). Chromium levels in the three samples were all found to be above the WHO MCL of 0.05 mg/L (>2X MCL). The levels of copper were also found to be over ten times the US EPA MCL of 1.3 mg/L. and chromium (>2X MCL), as well as high levels of zinc, sulfur, silicon, and calcium. Based on this chemical analysis, there is sufficient evidence to suggest that babash, beyond the effects of ethanol, may pose a public health risk to consumers.

DISCUSSION

Surrogate alcohol or unrecorded alcohol as it is known around the world is a threat to public health. The analyzed samples of babash showed a variance on levels of methanol, ethanol, arsenic, aluminum copper, iron and zinc. These results could be a single batch specific outcome, and could change in the next batch of babash, as producers do not use precise methodology for each production.

If improperly distilled at incorrect temperatures, the alcoholic beverage can be laden with impurities of carbons and metals that did not evaporate at their respective boiling point [18]. Methanol is hazardous to the human body if consumed at a rate of 2%/volume in liquid form can cause harmful effects on the liver leading to liver hepatitis and ultimately irreversible cirrhosis and possibly death if consumed in excess [19]. In the human body, methanol is converted to formaldehyde, which can subsequently effect the optic tract and lead to temporary or even permanently blindness if constantly consumed. Of the three samples analyzed, all three samples were well below the hazardous limit of methanol poisoning, however, sample 1 has a subsequently higher percentage (.1%/ volume) of methanol concentration compared to the other two samples (see Table 1). Although Sample 1 might be considered “safe,” as it is under the hazardous level, it can result in acute blindness.

Ethanol is the portion of the alcohol, which is consumed by humans, and is measured by ethanol percentage/ volume (proof). It is very subjective criteria to measure the quality of alcohol consumers are drinking, but instead measure the quantity of alcohol consumed. In the case of Babash, the variability in the three samples (Tables 1 and 3) shows that sample 1 (170 proof) is almost double the proof of the average rum (60-100 proof) and other two samples under the babash ‘moniker.’ The quantity (proof) of ethanol in legalized alcohol can be controlled to variable limits based on the manufacturer’s distillation process. However, in babash, as seen in the chemical analysis the variability between producers is all based on the distillation process and lead to serious health outcomes if not regulated properly. Excess ethanol consumption can lead to fatty liver (steatosis), which can progress to irreversible liver cirrhosis. Mentally, patients with ethanol poisoning will be confused, lack of movement (ataxia), signs of neuropathy, and a decreased respiratory rate which can lead to sudden death.

Aluminum is a neurotoxin and results in poorer psychomotor control and cerebral impairment leading to a decrease in IQ. While there is no agreed MCL for aluminum, chronic ingestion of aluminum has been linked to neuro-degenerative effects [21]. Altman [21] found that a water supply with excess in aluminum sulphate that was used in illegal alcohol production in England resulted in organic brain damage occurred.

Lead is a toxic metal that should not be found in the human body as once it gets into the bloodstream can cause renal failure, liver damage, and impaired hearing or cause mental retardation [20]. According to Morgan, Parramore, and Ethridge [17], the human lead toxicity level is 300 mg/dl, however, all of the samples of babash samples were <.05 mg/dl.

Excess iron can lead can also lead to neurological/physiological problems such as Parkinson’s disease [18]. Acute iron poisoning causes GI, cardiovascular, metabolic, hepatic and central nervous system toxicity [22] Liver is one of the organs most affected by cellular iron toxicity, but other organs such as the heart, kidneys, lungs, and the hematologic systems also may be impaired. Chronic iron overload, the deposit of iron into the heart may cause death due to myocardial siderosis

Cadmium poisoning can cause anaemia, emphysema or renal failure and cadmium may be a risk factor in the development of prostate (which is of interest in the Grenada Afro Caribbean population) or lung cancer.

Excess zinc inhibits the uptake of copper, which leads to aneurisms and cerebral dysfunction leading to increased risk of stroke. In addition, copper causes liver damage-hepatitis going on to cirrhosis. Excess copper spills into the liver, and leads to deposits in the RBCs, eye, and brain.

Finally, chromium was also found and known to impair kidney functions, reproductive capacity, hypertension, and hepatic dysfunction [20].

While the ethanol and methanol content is within safe limits the heavy metal analysis of the samples suggests that unregulated rum can have potential serious side effects.

CONCLUSION

Metal and chemical contamination is a problem when unregulated and poor quality control methods are used in the distillation process of the creating illegally produced alcohol [18]. Unregulated both in taxation and quality control Babash's demand has increased over the past decade and so has the number of illegal producers of the rum [23]. As a result of the analysis, there is variation in the chemical and metallic impurities there. Although none of the samples reached the hazardous or toxic limits found in the human body, they can still have acute and chronic effects on the body depending on the consumption rates and chemical content.

While the initial organic analysis provided optimistic results as a cheaper form of alcohol, with the ethanol and methanol levels within safety limits, the results of the heavy metals are of concern. The majority of results are below physiologically significant levels, however Aluminum and Copper are of some concern. These metals have significant mental and cognitive effects on the human brain. The limitation of this was that quantity of babash was not addressed. More research is needed to develop an evidence based protocol in considering the abovementioned concerns would potentially help reduce the potential harmful implications of babash consumption mentioned above.

Chapter 9

INFLUENTIAL FACTORS AFFECTING UNDERAGE DRINKING AMONG CARIBBEAN YOUTHS

***Nikita Cudjoe¹, MPH, Emmanuel Keku^{1,*}, MD, MSPH,
Cecilia Hegamin-Younger^{1,2}, PhD and Shelly Rodrigo¹, PhD***

¹Department of Public Health and Preventive Medicine, St. George's University,

ABSTRACT

Underage drinking is a problem among Caribbean youths, however little information is known of the interpersonal and intrapersonal factors that are seen in association with the consumption of alcoholic beverages. This article serves to highlight some socioecological aspects in the Caribbean that may contribute to underage drinking. Data was used from a regional survey conducted by Inter-American Drug Abuse Control Commission (CICAD). Interpersonal factors such as, increased shared meals between parent and adolescent decreases the risk of the adolescent engagement in underage drinking. Furthermore, good quality father-adolescent relationship, have shown to statistically significantly reduce underage drinking. Whereas, increase drinking habits exhibited parents and the increased number of peers who consume alcohol have shown to increase risk of underage drinking. A good mother-adolescent relationship and the adolescent's perception of the harmfulness of regular consumption of alcohol, have shown statistical significance. These results suggest that greater efforts need to be implemented at the intrapersonal and interpersonal levels in the Caribbean, to reduce underage drinking.

Keywords: adolescence, alcohol, underage drinking, Caribbean

INTRODUCTION

Globally, 14% of females and 17% of males engage in underage drinking, which is defined as the consumption of alcohol before the legal age [1]. In 2013, it was reported that, 35% of school aged children in the United States consumed alcoholic beverages within the 2last 30 days [2]. In the Caribbean 43% of adolescents 14 years or younger, 58% of 15-16 year olds and 17% of those 17 years or older engage in underage drinking [3].

The perceptions and beliefs by the adolescent are critical in understanding the contributing factors of underage drinking and its continuance into adulthood [4]. Adolescents perceive that drinking is associated with being recognized as an adult, hence they engage in such behaviours [5]. Although adolescents are quite knowledgeable of the increased risk associated with the consumption of five or more alcoholic drinks once or twice a week, alcohol consumption has increased from 38.2% to 40.7% between 2002 and 2011 [4], thus indicating that underage drinking continues to be an issue within this developmental age group.

Interpersonal factors such as parents and peers play a key role in social support and initiation of underage drinking [6]. A collapse within the support system or the involvement of parents and peers who consumes alcohol can result in the early onset of underage drinking that may further progress into difficulties due to ingestion of alcohol early adulthood [7]. It has been shown that the adolescent whose father drinks is at an increased risk of underage drinking [3,21], whilst the mother increases the risk to a lesser extent to 2.14 times [8]. Nevertheless, the consumption pattern of both parents may influence the adolescent's premature drinking habits. Despite the drinking habits exhibited by parents, the quality of the relationship between the adolescent and parents can serve as a protective factor against underage drinking [6]. Adolescents who feels respected and are familiar with a sense of belonging, within the family has shown to be an integral protective factor against deviant behaviours [9]. In addition to the adolescents "placement" within the family structure, the parents' type of disciplinary approach can promote or delay early onset of underage drinking. Parents who have a permissive attitude towards underage drinking while informing them about the dangers of alcohol usage, have shown to reduce underage drinking in comparison to an authoritarian approach whereby, consumption of alcohol is strictly prohibited without any communication of its harmfulness, leaving curiosity within the adolescent's psyche [5]. Dishion and Loeber [10], stated that adolescents who are closely monitored by parent(s) are at lowered risk of engaging in alcohol consumption and are less likely to have peers that also do so [11].

Despite parental influences, peers interactions, can too influence the adolescents to engage in underage drinking. Studies have shown that the adolescent's family interaction decreases and time spent with peers increases age the adolescent becomes older [12]. Thus, in search for acceptance by peers, adolescents become increasingly vulnerable to delinquency and substance abuse behaviour [13]. A 5.17 fold increased risk has been observed among adolescents who had friends who consumed alcohol [14].

Drinking alcoholic beverages during adolescence poses a public health issue due to lack of brain development which may result in increased disability-adjusted life years lost. Ingestion of alcohol during this developmental stage has been shown to significantly impact the adolescent's brain morphology causing deceleration or under-development of the brain

[15]. The lack brain development can result in, decreased sustained attention is experienced followed by delayed academic progression [15] which may further result in a lowered Grade Point Average and missed days among adolescent males [16]. A study conducted by the Centres for Disease Control and Prevention [17] findings suggested that 1 in 10 adolescents between 15 and 20 years drive under the influence moreover, and found a 17 times increased risk of being in motor accidents can occur when the adolescent drives under intoxication. Thirty – four (34%) percent of adolescents have reported being driven by their peers or family members who were under the influence of alcohol [18]. Difficulties in completing every day task due alcohol consumption in early adulthood has shown to be related to increased frequency of drinking alcohol during middle adolescent period [19]. Furthermore, an increased risk of 1.06 in developing cancer correlates to moderate drinking habits [20]. This current study aims to explore the adolescents' perception, parents' drinking habits and relationship with the adolescent as well peers' influence on underage drinking in the Caribbean, thus reducing the prevalence of underage drinking among the Caribbean islands.

METHODS

Secondary data was obtained from a regional cross sectional survey conducted by the Inter-American Drug Abuse Control Commission (CICAD). The survey assessed the prevalence of alcohol and drug use among nine Caribbean countries, as well as possible risk factors that may contribute to the adolescent's usage. Nine Caribbean countries were surveyed; Trinidad and Tobago, Antigua and Barbuda, Jamaica, St. Kitts and Nevis, St. Vincent and the Grenadines, Grenada, Guyana, St. Lucia and Haiti. To ensure random selection of participants, a two stage cluster sampling design was performed by secondary schools and later by classrooms (Forms 2, 3 and 5) which included pupils from between ages 12-16 years.

Fifteen questionnaire items based on alcohol use and possible risk factors were exclusively selected for the purpose of this study. The variables assessed were sex; age; parents' knowledge of whereabouts of the adolescent; number of meals in the company of their parents; parents' knowledge of close friends; reactions of the father and mother to the adolescent coming home drunk/tipsy; the relationship with father and mother; drinking habits of the mother and father; the number of the adolescents' peers that consume alcohol; the adolescents' perception of regular alcohol use to their health and the adolescents' perception of the harmfulness of getting drunk.

Data were analyzed Using IBM Statistical Package for the Social Sciences Version 23. Descriptive statistics were utilized to describe the sample population and alcohol consumption and comparisons between males and females were done using Chi Square analysis in relation to the variables. Lastly, logistic regression was used to estimate the influence of the intra- and interpersonal factors on adolescents who consumed alcohol.

RESULTS

The total sample included 19,376 students aged between 12 to 17 years from 10 Caribbean countries. The mean age was 15.4 years, with 46% being males and 21.4% of the sample group being predominantly from Trinidad and Tobago (Table 1). The highest proportion (39%) of the respondents stated their parents' marital status as married followed by the second highest as being single (26.6%). Furthermore, more than half (64.6%) of the study participants engaged in underage drinking, with 54.2% being female when compared to males (45.8%).

A large percentage in each gender reported that parents rarely knew of their whereabouts; females (80.6%) and males (62.0%). Forty – seven percent (47%) of males and sixty percent (60%) of female adolescents disclosed that their father would be extremely upset if they were to arrive home intoxicated. However, more adolescents (males 52.5%; females 61.0%) reported that their mother would be extremely upset in contrast to the father's reaction. When comparing the relationship between the adolescent and their parents, majority of males (48.4%) and females (51.1%) described the relationship existing between themselves and their father as moderate, but reported that the relationship with their mother as good (males 65%; females 59.9%). Whilst majority within each gender stated they had no friends who consumed alcohol regularly (males 45.8%; female 56.7%), there was a statistically significant difference of the number friends of adolescents who consumed alcohol between males and females ($p < 0.001$).

There was statistically significant difference ($p < 0.001$) of the perception of the harmfulness of getting drunk and regular consumption of alcohol between genders. More females than males had perceived that regular consumption of alcohol (males, 45.6%; females, 54.1%) as well as getting drunk (males, 55.5%; females, 61.1%) is very harmful. When considering the parents' reactions to the adolescent coming home drunk or tipsy, there was a statistically significant difference between males and females ($p < 0.001$).

There was no statistically significant difference between the relationship with the mother and the adolescent's consumption of alcohol ($p > 0.05$). On the contrary, the association between the father's relationship with the adolescent and drinking was statistically significant ($p < 0.05$).

The odds of underage drinking among adolescents who had meals with parents for 3 to 5 days and 6 to 7 days compared with those who had meals for 0 to 2 days per week was 0.76 (95% CI 0.66, 0.88) and 0.67 (95% CI 0.61, 0.74) respectively (Table 3). A protective effect was noted when comparing fathers who reacted extremely (OR 0.45; 95% CI 0.31, 0.63) or moderately (OR 0.57; 95% CI 0.40, 0.83) to knowledge of their child consuming alcohol in comparison to the father who was not upset. Adolescents were found to be 1.3 (95% CI: 1.01, 1.69) times more likely to drink alcohol when the perception of its harmfulness was moderate and 0.94 (95% CI: 0.73, 1.2) when adolescent's perceptions were very harmful in comparison to adolescent's perception that it was not harmful. Furthermore, adolescents who had one friend that drank alcohol have an increased risk of 1.9 (OR 1.9, 95% CI: 1.59, 2.29), whilst adolescents with some friends and a lot of friends has shown a further increased risk of 2.854 (95% CI: 2.57, 3.17) and 3.981 (95% CI: 3.22, 4.93) respectively.

DISCUSSION

In our study, the intrapersonal and interpersonal levels were assess to discover the possible influences on underage drinking. One of the fundamental aspects that initiates bond formation between the adolescent and parent are shared meals between adolescent and parent. From the analysis, it was observed that adolescents who has an increased number of shared meals with parents of 3 to 5 times and 6 to 7 times weekly showed a significant decrease risk of underage drinking by 24% and 33% respectively, in comparison to adolescents who had 0 to 2 shared meals. This can be related to the benefits of shared meals, which provides an open forum to building communication, monitoring as well as addressing issues that concerns the adolescent [21]. Additional studies have also shown to corroborate our findings, whereby increased number of meals together with the adolescent, decreases the risk of deviant behaviours including underage drinking and drug usage [22, 23].

Parents' reaction of moderate and extreme disdain, when the adolescent arrives home visibly intoxication has resulted as protective factors against underage drinking compared to parents who were showed no indication of disapproval. Our findings revealed that the father's

reaction was even a greater influence in reducing engagement of underage drinking of 55% (95%CI: 0.31, 0.63) when compared to a similar reaction by the mother is 45% (95%CI: 0.31, 0.63). This may be due to the stereotypical association that the father is disciplinarian of the household whereas the mother provides the comfort and assists with the emotional needs of the family [9]. Hence, the father reaction has a greater impact on the adolescent's consumption of alcohol. Other studies have discovered, however that parents with authoritarian tendencies have shown to increase high risk behaviours compared to parents with non – authoritarian attitudes [24].

The parent- adolescent relationship are critical elements during the adolescent's developmental phase which can deter them from a series of negative outcomes [25]. Having a moderate and good relationship, with the father significantly decreased the odds of underage drinking from 0.69 to 0.56 respectively in comparison to the adolescent who has a bad relationship with their father. Studies consistent with finding indicated that adolescents who have had their emotional needs met by their father fosters a father – adolescent connection, which have shown to prolong having to consume alcohol the future [26]. As such, the absence or existence of a good relationship between the father and the adolescent is an indicator in promoting or reducing underage drinking respectively. The mother's relationship showed no statistical significance in reducing underage drinking, thus does not impact adolescent consumption of alcohol.

Drinking habits exhibited by parents are related to underage drinking. In cases whereby the adolescent's father is moderate or heavy drinker have shown to increase the chances of the adolescent consuming alcohol by 85% and 103% respectively, compared to fathers who do not consume alcohol. The mother's drinking habits are also risk factors for underage drinking; with an increased odds of 63% as a moderate and 71% as heavy drinker. The father has a greater influence compared to the mother's influence on underage drinking. Fathers are more so the role models of the household, thus imitation of such behaviour are natural for the adolescent. The social learning theory can corroborate the findings of this study, whereby the learning process was facilitated by observation of the drinking habits exhibited by parents, followed by imitation of those behaviours by the adolescent [27].

The Health Belief Model (HBM) commonly serves as a template when addressing issues of behavioural change at an intrapersonal level. In this study, the construct of the HBM perceived severity was examined. Adolescents who are unaware of the harmfulness of getting drunk have shown a decreased odds (32%) of alcohol consumption when compared with adolescents who do not perceive getting drunk as harmful. On the contrary, when the perceived risk increased to moderate and very harmful there was no statistically significant difference in comparison to the perception of no risk. Invincibility is a key aspect within this developmental stage regardless of the consequences. Furthermore studies have shown that perception of the harmfulness of underage drinking is not sufficient to reduce the consumption of alcohol by minors [28], thus greater efforts should be made by using other constructs of the HBM such as perceived benefits.

There is an increased odds of alcohol consumption among adolescents who had a lot of friends (OR = 3.98; 95%CI: 3.22, 4.93) rather than some friends (OR = 2.84; 95%CI: 2.57, 3.17) when compared to adolescents with no friends. Social support of peers is important factors during adolescence, whilst too can be a burden. The Social Norms Theory can attest to our findings of increase number of friends, who consumes alcohol increases the risk of underage drinking [29].

This study has several limitations. Selection bias was introduced, since persons who attended school on the day of the survey were the included in the sample. Students who were absent may have different characteristics from those who were present. However, the random sampling of schools and form classes, allows for generalization of the wider population. The use of unweighted data of alcohol consumption of underage drinking between countries demonstrated a bias view. Furthermore, there was no controlling for confounders such as gender, socioeconomic status and ethnicity.

In conclusion, from our findings corroborating by similar studies that intra and interpersonal factors play a significant role in delaying the onset of underage drinking. Usage of all constructs of the HBM will provide a holistic approach in understanding and formulating intervention to address underage drinking. Furthermore, whilst both parents' negative attitudes are protective factors against underage drinking, the father's reaction is more of a protective factor compared to the mother based on the stereotypical role of the father figure. Thus, interventions should address the relations between the adolescent and father to delay the onset of underage drinking.

ABSTRACT

Traditional and non-traditional forms of alcohol advertisements are meant to entice adult consumers to drink as well as create a pipeline for new and upcoming drinkers, serving to establish brand loyalty through various promotions. While there has been much research of traditional and non-traditional forms of alcohol advertising, there has been little attention on the exposure of the byproducts of alcohol drinking on adolescents. The purpose of this observational study was to quantify the amount of indirect advertising, such as people drinking in public and alcohol posters, Caribbean children and adolescents are exposed to during an average day walking home from school. Two neighborhood routes students use to walk home were identified; one route for elementary school children and a second for high school students. Researchers walked the routes at the time students were dismissed from school on a weekday. The results demonstrate that

* Corresponding Author's Email: chyounger@ghc2.com.

children as young as 6 years old are exposed to many forms of indirect alcohol advertising.

Keywords: alcohol advertisements, adolescent alcohol consumption, public health, Caribbean

INTRODUCTION

Unhealthy alcohol consumption accompanied with abuse of alcohol is a significant problem globally. According to data obtained from the World Health Organization [1] in 2010 the global consumption of alcohol was equivalent to an estimated 6.2 liters of pure alcohol consumed per person aged 15 years or older; this is about 13.5 grams of pure alcohol daily. Despite the rise in the daily consumption of alcohol globally, there has been an alarming increase in underage drinking. In 2013, the National Institute on Alcohol Abuse and Alcoholism (NIAA) reported that 35.1% of 15 year olds have consumed at least one drink in their lives. In addition, approximately 8.7 million people within the ages 12-20 years indicated drinking alcohol in the past month. Of these current drinkers, 16% were heavy drinkers [2].

According to a 2008 WHO-initiated Global School-based Student Health Survey conducted in Grenada, approximately 45.6% of secondary school students reported having at least one drink in the previous 30 days and about 27.3% reported having been intoxicated at one point in their life. According to a study conducted by Shayota [3], who investigated the prevalence of alcohol use among 1542 secondary school students aged 11-16 years, it was discovered that the overall prevalence of alcohol use was highest among males; however, there was a growing rise in females consuming alcohols. An estimated 31.6% of males versus 29.4% of females in the age 11-12 cohort group were currently consuming alcohol. An increase to 44% amongst males in the 13-14 age group versus 37.9% for the females. Lastly, the highest prevalence was in the 15-16 age group, with 67.2% of males and 54% of females currently consuming alcohol [8]. Updated data from a 2013 Global School-based Student Health Survey indicated that around 70% of students had reported having a drink in their lifetime and 28.5% of students of the ages 12-13 had their first drink of alcohol compared to 22.8% at 10-11 years and 22.9% at 14-15 years.

The promotion of alcohol and targeted advertisement is universal as it exist in almost all countries with the exception of some of the countries with predominantly Muslim populations and where strong regulation limits focusing on adolescents and young adults [4]. Such case scenarios occur particularly among the public advertisement of alcohol across the Caribbean, where many island nation's economies and the promotion of tourism aggressively promote rum, beer and other exotic alcohol beverages. The production and promotion of alcohol are entrenched into the Caribbean's history and transcends into many cultural experiences. Thus, there is an ever presence and ease of availability of alcohol, and alcohol promotions may serve as encouragement for alcohol consumption in some individuals, such as adolescents and young adults. Within such contexts, factors such as parents and peers, are believed to influence alcohol consumption [5]. Other influential factors are alcoholic advertisements on television, which are disguised with appealing settings and memorable messages that may remain with the viewer. Other than television messages, alcohol advertising is observed

through products, special promotions, sponsorships of musical, educational and sporting events, hats, clothing, and other merchandising products. The convenience of having sale promotions such as 3 for \$10 dollar beers and “two for one” discount events at local bars, serve as advertisements to increase consumption [6]. The convergence of these issues in the Caribbean was the basis for this study, which explores the role of advertising as it relates to alcohol exposure among elementary and high school students (6-18 years) in a Caribbean island, Grenada.

Studies conducted have supported the theories that there is a lack of social control and education on the harms associated with alcohol consumption because it is highly integrated into the culture and, as such, traverses age and generation. Longitudinal studies have been conducted to support the theory that exposure to alcohol advertising results in a strong belief about drinking and is positively associated with increased adolescents and early adulthood alcohol consumption [7].

While alcohol consumption is a key component of cultures around the world, in the Caribbean, specifically Grenada, 31%-59% of children consume alcohol for the first time by the time they are eleven and half years of age. By age fourteen, 75%-86.5% of children report they have consumed at least one drink of alcohol [8, 9]. Adolescent brains are more vulnerable to the effects of alcohol compared the brain of an adult [10]. Research suggests that consumption of alcohol from age 11-14 years increases a child’s risk of developing dependent behaviors [10] and suffering from the cognitive effects of neurodevelopmental damages [11]. Natures versus nurture theories are instructive in this regard. Appreciably, while genetic components of human beings determine many factors of development, influences of environmental exposures cannot be ignored.

The impact of alcohol advertisements on the age of initial alcohol consumption is debatable. The intent of alcohol advertisements may be to promote brand choice and not alcohol consumption; however, the high frequency of alcohol advertisement in the environment inevitably influences the drinking choices of children [11] and possibly the regularity with which they drink. The goal of this study was to raise awareness of a child’s potential exposure to alcohol advertisements and alcohol consumption. The purpose of this study was to examine the exposure of school-aged children (in elementary and high schools) in Grenada to advertisements promoting the use of alcohol on a typical school day. To accomplish this, three objectives of this study were to observe and document the number of alcohol advertisements (posters, signs, umbrellas, bottles, bottle tops), stores selling alcoholic beverages, and individuals drinking alcohol.

The Law that overlooks alcohol consumption in Grenada is the Liquor Dealer License Act Chap 174. Within this legislation, there are rules on distribution, sale hours, limitation of drunkenness, but the legislation lacks in certain areas that should be addressed. There are not any regulations set in place that address advertising of alcoholic products, sponsorships and promotions. Also, there is a lack of regulation of health warning labels on alcoholic advertisements and bottles and containers that are produced within Grenada. Assessment of current legislation shows that the amount of support towards limiting the exposure and availability of alcoholic beverages is restricted and inadequate. Added to that, the sale of alcohol to minors remains, by and large, unregulated. As such, children and adolescents are frequently sent by adults to purchase alcohol. Granted that alcohol is a sustainable source of income, given the rate of consumption, proprietors are not inclined to turn away anyone from purchasing alcohol.

BACKGROUND

In the Caribbean region, there are a variety of factors that encourage people to heavily consume alcohol thus further exacerbating the problem of excessive alcohol consumption. Generally, alcohol is utilized to alleviate the societal pressures and physical stresses of working under the characteristic hot and humid Caribbean climate and provides a means of psychological escape [12]. In addition to this, alcohol is widely used in the region as a popular beverage in social occasions. This is exacerbated by the culture of 'fete' that is inherently Caribbean. Another factor influencing heavy alcohol consumption in the region is the cultural norm of consuming alcohol after work aside from being limited to social functions. The region's past also seems to fuel this issue because historically speaking the Caribbean islands are deemed as a place where people take vacations and participate in heavy drinking to alleviate the daily stresses of life. It is important to note that according to research carried out by Legion, Gregorowicz, and Jolly [13], it was established that a rise in income substantially increases the amount of alcohol consumed and the consumers have a tendency to upgrade from the local illicit brews towards heavily consuming the more refined drinks. Furthermore, most Caribbean nations were once European plantation colonies that produced sugarcane, molasses and rum as export products throughout the world [12].

Alcohol advertising is a very effective method of targeting current and future consumers on the availability of alcohol and alcohol related products. Alcohol advertising is responsible for initiating drinking among adolescents commencing at a young age and enhancing the transition from experimental drinking to hazardous drinking [14]. Given the problem of underage drinking, there are a multitude of factors, which contribute to this problem. These problems include access to cheap alcohol, access to alcohol from parents, long periods of unsupervised time, access to money to spend, early introduction to alcohol, alcohol advertising, poor educational achievement and truancy, exposure to adult binge drinking and alcoholism, a culture where drinking is the norm and is encouraged, peers who indulge in alcohol and bullying [16]. Taite, found that young adults (15-23 years old) had a high recall of advertisements on television for top beer and distilled brands. This recall was a factor found to predict drinking outcomes [14].

Chai and Politi [15] noted a gender difference in the messages received by alcohol advertisements. Young girls tend to absorb message more quickly and are more prone to influences because of the social and emotional effect of the ads. Most of these advertisements present messages of increasing attention from men, obtaining a successful life and appearing more attractive towards people of the opposite and same sex if one consumes alcohol. Thus, making young girls more susceptible to consuming alcohol from an early age [15] if one consumes alcohol.

Most of the literature provided state there is a link between alcohol advertising and early and increased drinking among youths. Despite the numerous supports to this claim, there are some studies, which refute this. However, despite the lack of conclusive evidence of alcohol consumption being influenced by alcohol advertising, there are studies, which show that adolescents are very vulnerable to the effects of advertising [17]. Adolescents who have higher exposures to alcohol advertising have a higher probability of developing positive attitudes and beliefs about alcohol. Also, the exposure to alcohol advertising results in

increasing the likelihood of early initiation of adolescent alcohol use and a rise in the amount of alcohol consumed [18].

METHODS

This observational study examined the frequency of alcohol exposure through direct and indirect advertising among elementary and high school students, separately. One elementary school and one high school were purposefully selected based on the major routes the students used to travel to and from school. Students were observed as they exited the school on the main roads and made their way home. Elementary school students observation stopped at the point the route traveled was not the main road. The route observed was approximately half a mile in distance. High school students were observed on their route from school to the main bus station, where students take separate buses to their home. The high school selected was in walking distance, approximately half a mile in distance, to downtown St. George. Many high school students travel the public bus system to their villages within and outside St. George. Because the high school system is one where you select the high school, students can travel from all parts of Grenada to attend high school in Grenada.

To quantify the frequency of advertisements to which elementary and high school students are exposed, an observation list was developed. The observation list included: alcohol advertisements, including signs, umbrellas, and posters; individuals drinking in public spaces, which included open-air bars; stores and stands selling alcohol; and other, to capture any unexpected forms of advertisements.

Two groups of observers collected data. One group observed the elementary route on a Wednesday and the second group observed the high school students on a Friday. Both groups collected data at the time students were walking home, which was 3:00 pm for the elementary students and 2:00 pm for the high school students. The results of the observation lists were compared to determine the degree of agreement. In the case of a disagreement, the observers discussed the form of advertisement and came to a consensus in its resolution.

RESULTS

Overall, both elementary and high school students are exposed to various forms of alcohol advertisements while they walk from school to their homes or in the cases of those travelling to the bus station. Table 1 presents the frequency of advertisements to which the students are exposed. All students were exposed to signs, umbrellas, public drinking and bottle caps. What was unexpected was both groups noted the extremely high number of labeled bottle caps on the ground of the routes traveled. With respect to the agreement of observers, the number of bottle caps was an issue, because not all observers had the same number of observed bottle caps, Table 1 presents the lowest number of bottle caps recorded. This is also true for the number of people who were consuming alcohol in public.

Table 1. Summary of checklist: Frequency of alcohol advertisements

	High school students	Elementary school students
Signs	11	6
Umbrellas	3	2
Public drinking	33	11
Vendors	12	10
Bottle caps	70+	35+
Brewery	0	1

Elementary Student Route Observations

From the checklist, it is evident that elementary school students are exposed to alcohol advertising. On this route, children passed a brewery, large billboard and bars that have open windows. In addition, the restaurants, provision stores, and open kiosks had alcohol visible at the eye level on the shelves. Additionally, none of the billboards advertising alcohol had any messages emphasizing the practice of healthy alcohol consumption behaviors’ such as not driving or operating machinery under the influence of alcohol. Moreover, they neither contained messages emphasizing the use of alcohol from the legal age of 18 years nor the negative effects associated with unhealthy alcohol consumption. There were absolutely no messages present to educate the consumers and raise awareness. Also, in the residential areas, there were small posters, stapled to power poles, along the routes used by the children advertising party functions with drinks offered and special discounts to purchase multiple drinks during one transaction. In addition to this, there were playing fields, where residents commune during the evening hours to hold party functions and play sports. This is another notable means of directly exposing children to alcohol and which contributes to indulgement at an early age. It is vital to point out that the public buses the elementary students utilized to travel home play loud Soca music, which contain messages of consuming alcohol. While walking on the route, the observers noticed a large number of bottles and bottle caps in the street. Also observed were children picking up the bottle caps and playing with them.

High School Student Route Observations

Along the high school student route were many stores, an outdoor produce market and kiosks serving alcohol, a shopping mall where cruise ships dock and which has stores that sell alcohol as well as alcohol paraphernalia. This is an area where high school students congregate to socialize and to wait on parents and guardians. Inevitably, these students would browse around the stores and, as a result, be exposed to alcohol advertisement. On Friday, there were many activities as it is the start of the weekend and adults drink more. Across the street from the mall entrance is a wall of advertisements, a bar and a library. It is interesting to note that to get to the children’s library one had to walk through the bar. The end point of the route is the bus station, which is the final point before continuing their journey home on the public bus. The bus station is a large structure similar to a 2-story parking structure that is open on all sides. In the bus station, there are kiosks where alcohol and snacks are sold. In addition, the bus station is where many alcohol advertisements are placed. Advertisements are

in the form of posters, signs and scattered bottle caps. The bus station also has men who are drinking in front of the bus station and inside the bus station.

DISCUSSION

This study provides evidence that elementary and high school students are exposed to alcohol outside the home from an early age. As alcohol is part of the culture, these indirect and by-products of direct marketing serve as messages that alcohol is readily available and accessible. As such, they also serve to strengthen the culture of alcohol consumption; having a potentially significant impact on underage drinking. Notably, alcohol is ingrained in the culture of Grenada. Similar to many other areas where alcohol is embedded in the culture, exposure to alcohol is a part of life from cradle to grave. A high frequency of alcohol advertisements on secondary children's route to and from school is therefore not surprising. On the Friday observed, the most alcohol advertisements were documented at the main bus station in St. George. Although the bus station is a public place, it is important to point out that the audience at the bus station at certain times each week day is primarily youths. Therefore, students may travel from areas of low-density alcohol advertising to areas of high density; where there is the constant bombardment of alcoholic advertising. This sort of constant enticement coupled with the pervasive alcohol culture creates a serious public health concern. Because there is no "school bus" and students use the public buses for transportation, the St George bus station is the school bus pick up and drop off for hundreds of Grenadian children attending school in St. George. Alcohol drinks can be purchased in the terminal and at nearby bars and street vendors.

A broad conclusion is that unconsciously or consciously children are exposed to a variety of alcohol advertisements on their walk to and from school. We venture that these promotions can and do impact their attitudes to and consumption of alcohol.

Alcohol advertisements can seep into a Grenadian child's life frequently to and from school will be as they are exposed to multiple alcohol advertisements, individuals drinking alcohol, and stores and kiosk stands selling alcohol on the student's walking route home.

The constant and consistent existence of alcohol promotion and purchasing opportunities makes it extremely difficult to create counter public health arguments and messages to discourage the consumption of alcohol, especially among young people. First, many points of purchase rely on alcohol sales to make a profit and support their livelihood of their families. Second, there are multiple points at which individuals can access alcohol, making it impossible to limit it to locations where school children are less likely to frequently visit. Third, the price of alcohol is very cheap; at times as cheap as purchasing bottle water. Fourth, the rum distilleries and beer breweries financially support many social events frequented by students, inclusive of sporting and educational events. Finally, these companies also advertise during prime time on television. A notable example is during the news broadcasts advertising alcohol. As a professional practice, teachers encourage their students to listen to and report on current issues; the news broadcasts being important sources of information. Consequently, students, during what was aimed at educational objectives, would be exposed to alcohol promotions. These factors are hurdles that must be overcome to limit young adult consumption.

Exposure to alcohol advertisements has negative implications on adolescents' preferences for alcohol and subtly encourages consumption [7]. Various alcoholic bottle caps are left in public spaces in Grenada and collected by children. These artifacts have the potential to incite interest in alcohol and to encourage consumption. In a resource-limited country where alcohol is tied to the economy and culture, it is a challenge to initiate policies and programs that reduce the prevalence of elementary and high school students drinking. It is better to have a weak policy, which is consistent with the cultural values and minimally impacts the revenue of established vendors that is enforceable than a strong policy that is an unenforceable one. Any attempts at programs and policies should therefore preferably be proactive, focusing on delaying the age of initiation of first drink rather than reactive, reducing the prevalence of youth drinking.

In developed countries tackling youth indulging in alcohol, the formulation and enforcement of policies governing the price of alcohol, location, density, operating hours of sale outlets alongside regulation of the alcohol market will have a greater impact than the simple ban of alcohol advertisements. In addition, enforcing harsh penalties and strict licensure requirements will assist in discouraging youth in engaging in hazardous drinking [17]. In a developing country where alcohol is connected with the economy, it is better to formulate policies and programs that are consistent with the values and culture, and do not impact the revenue that is generated from the local business owners.

Trinidad and Tobago, West Indies

ABSTRACT

Over the past 25 years, the aviation industry has been motivated by the need to reduce accidents of which 95% is attributed to human error. This study assessed Caribbean pilots on their Aeronautical Decision Making (ADM) knowledge and skills and evaluated their ability to identify risk factors and make appropriate decisions with exposure to alcohol consumption. Design and methods: Cross sectional study utilizing an electronic survey to members of the Trinidad and Tobago Airline Pilots Association (TTAPA) that attended the 2015 annual general meeting. The survey collected data on pilots' career background, ADM knowledge, risk assessments and decision process in aviation case scenarios. Results: 110 pilots participated in the study among which were 103 (94%) males, with an average age of 47 years (range 24 – 59 years). 47 pilots were locally trained while 63 were foreign trained with all having received ADM training and continued training. Average number of logged flight time was 9,347 Hobbs (range 541 – 23,441) and routes flown were mainly the Caribbean and the Eastern coast of North America. Effects of alcohol of takeoff and climb and landing was identified by 23.4% and 24.1% of pilots as the most incident prone and ADM dependent phases of flight. 94% of pilots accurately identified alcohol consumption as contributing to anti-authority, impulsivity, invulnerability, macho and resignation as hazardous attitudes. Further operational pitfalls associated alcohol consumption with peer pressure (80%), mind set

(74%), get-there-it is (51%), duck-under-syndrome (21%), continuing visual flight rules into instrument conditions (14%) and checklist neglect (7%). Conclusions: Alcohol consumption was assessed to be a risk factor that affects ADM as a critical skill set for pilots to protect the safety and lives of passengers than use air travel as a means of transportation.

Keywords: aviation safety, aeronautical decision making, alcohol in flight, Caribbean pilots airmanship

INTRODUCTION

The International Air Transportation Association (IATA) projected that two billion passengers will use air transportation to fly by the year 2024 [1]. Furthermore, IATA recognized there are over 104,100 pilots and 650,000 flight crew currently servicing the expanding aviation industry. Additionally, the potential risk to ground communities and infrastructure positions aviation as a significant global population based experience and potential for significant adverse public health consequences [2]. The risk potential that aviation poses has allowed for the establishment of a safety management system for aviation, which is primarily dependent on the health and safety of pilots [3]. Aeronautical Decision Making (ADM) is decision making in the unique environment of aviation, which comprises a mental process that pilots use to consistently determine the best course of action in response to a given set of circumstances [4].

Alcohol consumption is associated with various cultural and social practices such as celebrations and mourning traditions [5]. Alcohol beverages are used by many to “unwind” or relax, or act as a social “icebreaker” as it alters one’s mood by decreasing inhibition [6]. Alcohol consumption is widely accepted and has its genesis as a “rite of passage” into adulthood [7]. While alcohol consumption is an accepted social activity, piloting an aircraft is a highly demanding cognitive and psychomotor task, which takes place in an inhospitable environment of airline, passenger, maintenance and weather stress. Alcohol consumption is considered a sedative, hypnotic and addictive drug, which is rapidly absorbed from the stomach and intestines and transported by the blood throughout the body [8]. The effects of alcohol vary considerably from person to person and are influenced by variables of gender, body weight, rate of consumption (time) and total amount consumed (volume) [9]. Further, the rate of alcohol elimination from the body is fairly constant regardless of the amount consumed, which allows for effects to be sustained from 48 to 72 hours after consumption [10]. The majority of the adverse effects produced by alcohol consumption relate to the brain, eyes and inner ear, which are three crucial organs to pilots [11]. Brain effects include reduced reaction time, reasoning, judgment and memory as alcohol reduces the ability to utilize oxygen [12]. Specifically for pilots, the effects of alcohol on the brain are magnified with simultaneous exposure to altitude characterized by decrease partial pressure of oxygen. Visual impairments include eye muscle imbalance which leads to double vision and difficulty focusing and inner ear effects include dizziness and decreased hearing perception [13]. Pilots may also be exposed to conditions of sleep deprivation, fatigue, medication use, hypoxia, night flying or severe weather that can further magnify the negative effects of alcohol [14].

Figure 1. Effects of alcohol consumption on various stages of flight.

Studies on how alcohol affects pilots' performance have shown impairment in their ability to fly an Instrument Landing System (ILS) approach, fly Instrument Flight Rules (IFR) or even perform routine Visual Flight Rules (VFR) flight tasks [15]. The number of serious errors committed by pilots is shown to be dramatically increased at or above concentrations of 0.04% blood alcohol [16]. General aviation pilot fatalities reported by the Forensic Toxicology Research Section of the Federal Aviation Authority (FAA) Civil Aerospace Medical Institute identified Blood Alcohol Concentration (BAC) levels of 0.04% or more among an average of 8.9% of pilots [17]. The information based on analysis of blood and tissue samples from pilots involved in fatal aviation incidents demonstrates the need to attend to alcohol consumption in the aviation industry. The use of alcohol is regulated by civil aviation authorities around the world. The Federal Aviation Regulation (FAR) 91.17 is used to regulate the alcohol and drug use among pilots [18]. FAR 91.17 states that no person should operate or attempt to operate an aircraft within 8 hours of having consumed alcohol, while under the influence of alcohol, with a BAC of 0.04% or greater or while using any drug that adversely affects safety [19].

This study examined the ADM knowledge and skills based on an assessment of exposure to alcohol consumption among pilots. The objective was to understand the level of awareness of the potential risk to pilots, identify the main risks that require ADM among pilot as well as promote for effective alcohol regulation and health and safety for the Caribbean aviation community.

METHODS

The study population consisted of pilots who serve as active members of the Trinidad and Tobago Airline Pilots Association (TTAPA). Pilots that attended the 2015 Annual General Meeting (AGM) were invited to participate in the study. The study comprised of an electronic survey compartmentalized into five sections including the following:

Section 1: Background

Age, gender, location of training, whether ADM was years as a pilot, number of logged hours, routes flown, aircraft(s) flown.

Section 2: ADM Knowledge

- Identify the various phases of flight and what are the accidents associated with each phase.
- What are the five hazardous attitudes of pilots?
- Categorize the steps for good decision making.

Section 3: Risk Assessment

- What are the likelihood categories of risk in aviation?
- What are the levels of risk severity for aircrafts and passengers?
- What are the elements of risk mitigation in aviation?

Section 4: Case Scenario

Describe the process used and decisions made in each of the following scenarios:

1. A commercial jet pilot had only four hours of sleep the night before and was asked by the manager to fly to a meeting in a city 750 miles away. The reported weather was marginal and not expected to improve.
2. A pilot landing a small airplane just after a heavy cargo jet had departed a parallel runway. The pilot assumed that wake turbulence would not be a problem since landings had been performed using similar circumstances. Due to a combination of prevailing winds and wake turbulence from the heavy jet drifting across the landing runway, the airplane made a hard landing.
3. During a preflight, a pilot noticed a small amount of oil dripping from the bottom of the cowling. Although the quantity of oil was insignificant at the time, the pilot delayed a commercial jet liner to have a mechanic check the source of the oil.
4. On a cross Atlantic flight in marginal weather conditions, a pilot calculated the groundspeed and determined that the airplane would arrive at the destination with only 25 minutes of fuel remaining. The pilot was determined to keep on schedule by trying to mix the fuel supply instead of diverting to land for refueling. The flight landed on time with a low fuel state.

Section 5: Alcohol Consumption

- Do you consume alcohol?
- Is alcohol consumption done within 8 hours of flight time?
- What are the alcoholic beverages consumed within 8 hours of flight time?

Pilots who agreed to participate completed the survey at a computer terminal where responses were submitted and received in an electronic dataset that was analysed and reported.

RESULTS

110 pilots participated in the study of which 103 (94%) were males with an average age of 47 years (range 24 – 59). 47 (43%) of pilots were locally trained while 63 (57%) were foreign trained with 100% of pilots having received ADM training on the regulations and risks associated with alcohol consumption. The average number of logged flight time was 9,347 Hobbs (range 541 – 23,441) in routes flown across the Caribbean and the Eastern coast of North America. There were also 16 (15%) of pilots who reported incidents that were not fatal but was ADM related and occurred during their aviation careers.

Alcohol consumption was associated with effects on airmanship across different phases of flight including takeoff/climb, cruise and landing (Figure 1) as well as ADM operational pitfalls such as peer pressure, mindset and “get there it is” in commercial flying (see Figure 2).

All pilots responded to the case studies where ADM knowing and application was required to provide an accurate decision. The responses and pilot’s performance were rank as either adequate or not based on the required course of action for each case study. Pilots were assessed as adequate on the case studies ranging from 88% accurate in Case 2 to 100% accurate for Case 4 when compared to the standard ADM operational procedures expected. Figure 3 represents the performance of the pilots for each case.

Figure 2. Effects of alcohol consumption on ADM.

Figure 3. Performances in case study assessments.

Alcohol consumption was also assessed among pilots and was differentiated into flight time and non-flight time exposures. 84% of pilots reported alcohol consumption during non-flight time while 34% of pilots indicated consumption was within the 8 hours of flight time. Table 1 represents the alcohol consumption characteristics of the surveyed pilots.

The frequency of alcohol consumption among pilots who consumed alcohol within 8 hours of flight time was further evaluated. 76% of pilots who consume alcohol within 8 hours of flight time consumed 1 drink while 3% reported more than three drinks. The distribution is represented in Figure 4.

The assessment of alcohol consumption also surveyed the type of alcohol beverages consumed by pilots and ranged from whiskey, rum, vodka, beer, wines and cocktails. The frequency distribution of types of alcohol beverages consumed is reported in Figure 5.

Table 1. Alcohol consumption among pilots

	No of Pilots (%)
Alcohol consumption	92 (84%)
Alcohol consumption with 8 hours of flight time	37 (34%)
Alcohol consumption among male pilots	92 (89%)
Alcohol consumption among female pilots	0
Alcohol consumption among local trained pilots	37 (100%)
Alcohol consumption among foreign trained pilots	0
Alcohol consumption and its impairment of ADM	0

Figure 4. Number of alcohol drinks consumed within 8 hours of flight time.

Figure 5. Distribution of alcohol beverage type consumed.

DISCUSSION

The majority of pilots surveyed were males that were significant they reported risk behavior of alcohol consumption within eight hours of flight time as opposed to their female counterparts. Locally trained pilots were also reported to be the ones that consume alcohol within 8 hours of flight time. The risky behavior of alcohol consumption within 8 hours of flight time was associated with locally trained male pilots. This risk profile is important towards identifying intervention strategies towards reducing at risk alcohol consumption among pilots. Additionally, 16 pilots, all male and locally trained reported having been part of incidents that was assessed as a compromise of ADM standards and operational procedures. Furthermore, all 16 pilots with previous incidents reported as having consumed alcohol within 8 hours of flight time. Alcohol consumption maybe associated with pilots with a history of aviation incidents.

ADM standards and operational procedures were well established and assessed as adequate among participating pilots with accurate decisions submitted based on aeronautical challenges presented. ADM and adverse consequences as a result of alcohol consumption was identified for the takeoff, cruise and landing phases of flight. The pilots in identifying the challenging phases also noted the most cognitive and psychomotor active phases of flight, which may be compromised with exposure to alcohol consumption. Peer pressure was the most reported consequence of alcohol as pilots identified as alcohol consumed seem to be familiar with each other and served as a pressure to continue to engage in the behavior among each other. Alcohol was also referred to as influential to the mindset of pilots, which would serve to influence their ADM skills set.

The surveyed pilots while representing an estimated 25% of pilots as part of the Trinidad and Tobago Airline Pilots Association (TTAPA) should be considered as representative of the alcohol consumption behaviors of pilots. Guidelines from the Trinidad and Tobago Civil Aviation Authority (TTCAA) and respective airline operators must provide assurance that pilots are maintaining the FAR 91.17, which is critical to the safety of the air travel passengers and the Caribbean aviation industry.

CONCLUSION

The risk profile for alcohol consumption among pilots in the Caribbean are locally trained males who are more likely to have a history of an aviation incident. ADM standards and operational procedures were however well established and practiced. Education and attention to regulations should be strengthened to maintain the occupational health of pilots and the safety of their passengers and communities that may be affected.

**ASSESSMENT OF HEALTH-COMPROMISING
BEHAVIOR PREVALENCE AND CLUSTERING AMONG
GRENADIAN ADOLESCENTS: FINDINGS FROM THE
2008 GLOBAL SCHOOL-BASED STUDENT
HEALTH SURVEY**

ABSTRACT

Involvement in health-compromising behaviors amongst adolescents has serious, adverse implications for the individual, community and the public health system. While several studies have assessed the prevalence and clustering of health-compromising behaviors among youth, to the best of our knowledge, no such investigations have examined this issue within the Caribbean island nation of Grenada. As such, our aim was to assess health-compromising behavior (tobacco, alcohol, and drug use, gang involvement, and sexual activity) prevalence and clustering among Grenadian adolescents based on data obtained from the 2008 Global School-based Student Survey on Health. Alcohol consumption was the most commonly cited health-compromising behavior (62.4%), followed by sexual intercourse (25.1%) cigarette smoking (22.5%), drug use (15.7%), and gang involvement (13.5%) amongst all participants surveyed. Statistically significant relationships were evident between nearly all pairs of health-compromising behaviors for both males and females; we thereby conclude that behavior clustering was evident amongst Grenadian youth.

INTRODUCTION

Involvement in health compromising behaviors including, though not limited to, cigarette smoking, alcohol and illicit drug use, sexual activity and gang involvement are not confined to particular adolescences in any one geographical region but are rather a global public health concern [1-10]. Interestingly, the clustering of these behaviors, defined as involvement in multiple concurrent activities, has become increasingly evident.

It is widely accepted that adolescence is a challenging transitional period in one's life. Imperative is that many behaviors established during these formative years persist through adulthood. Adolescent morbidity and mortality are most frequently the result of preventable behavioral, environmental and social factors, as opposed to pathologic disease [11, 12]. The adverse effects of these health-compromising behaviors should not be underestimated [10, 13].

While several studies have been carried out to assess the clustering of health compromising behaviors within the United States [14-19], only one such study was identified, which evaluated these factors within the Caribbean region at large [16]. As such, this paucity of data has rendered gaps in our knowledge and understanding of health-compromising behavior among Caribbean youth.

The aim of this study, therefore, was to assess health-compromising behaviors (tobacco, alcohol, and marijuana use, violence, gang involvement, sexual activity) among Grenadian youth. To achieve this aim we evaluated the prevalence and clustering of health-compromising behaviors among Grenadian secondary school aged students from data obtained from the 2008 Global School Based Student Survey on Health. Also examined were the role of drug use and sexual intercourse involvement as precipitating factors to engagement in additional health-risk behaviors.

Assessment of health compromising behavior prevalence and clustering within specified populations is essential for the establishment of health promotion programming [9] and overall improved health status of a nation. We anticipate that these findings will advance the current understanding of health-risk behavior trends and adolescent behavioral development among Grenadian adolescents. Moreover, we suspect that these findings will subsequently guide public health prevention and intervention programs of the future.

METHODS

The current investigation involved a secondary analysis of data obtained from the 2008 Global School Based Student Health Survey, which was administered to students' aged 11-16 attending Grenadian secondary schools. The GSHS was developed by the World Health Organization (WHO) in collaboration with the United Nations Educational, Scientific and Cultural Organization (UNESCO), the United Nations Children's Fund, and the Joint United Nations Program on HIV/AIDS with technical support provided by the Centers for Disease Control and Prevention (CDC). This collaborative surveillance project was designed and implemented to support the ongoing collection and assessment of behavioral risk and protective factors in 10 fundamental areas, across all countries served by the United Nations in order to develop priorities, establish programs, and advocate for resource allocation [20].

Country-specific data, including questionnaires and fact sheets, are made publically available from the WHO and CDC and have been cited elsewhere in peer-reviewed literature [21-24].

The GSHS utilized a standardized scientific sample selections processes and a common school-based methodology whereby a 2-stage cluster sample design was employed to produce data representative of all students in Grenada. During the first stage, schools were chosen with probability proportional to enrollment size. During the second stage, individual classes were randomly selected with all students enrolled in the class being eligible to participate. Core questionnaire modules, and a combination of core- expanded and country-specific questions were administered on a computer scannable answer sheet in Forms 1, 2, 3 and 4, during a single regular class period. The 85-question, self-administered survey, conducted on 1,542 Grenadian students, ages 11-16, yielded a 95% school response rate, 82% student response rate and 78% overall response rate [20].

Measures

The following five health-compromising behaviors were included in analysis: sexual intercourse activity, cigarette smoking, alcohol consumption, drug use and gang involvement. The questions used to assess these five health-compromising behaviors are described in Table 1. Indicating yes to gang involvement or sexual intercourse was taken as indication of behavior engagement. Endorsing use of cigarettes or alcohol consumption one or more times in the past 30 days or drug use within the course of one’s life was accepted as indication of use and therefore behavior involvement.

Data Analysis

The prevalence of each health compromising behavior was calculated, stratified by gender and age category: ≤ 11 , 12-13, 14-15, ≥ 16 years. To assess the relationship between health-compromising behaviors, amongst girls and boys, odds ratios were calculated. To address the hypotheses that drug use and engagement in sexual intercourse are associated with initiation of additional health-compromising behaviors, relative risks were calculated. Confidence intervals were calculated for both the odds ratios and relative risks. All analyses recognized a p-value < 0.05 as statistically significant. All outputs were generated via SPSS version 19.

Table 1. Survey questions measuring health-compromising behavior

Sexual Intercourse Activity	Have you ever had sexual intercourse?
Gang Involvement	Do you currently belong to a gang or violent group?
Cigarette Smoking	During the past 30 days, on how many days did you smoke cigarettes?
Alcohol Consumption	During the past 30 days, on how many days did you have at least one drink containing alcohol?
Drug Use	During your life, how many times have you used drugs, such as marijuana?

RESULTS

The study population under investigation included 1,542 students attending Grenadian secondary schools. A total of 1,521 students were included in this analysis as they met inclusion criteria for selection by responding to the specified survey questions under investigation (including but not limited to age and gender classification). Thus, a total of 681 male and 840 female students participating in the 2008 GSHS were included and ranged in age from 11-16 years.

Males were determined to have a higher prevalence of involvement among all five health-compromising behaviors across all 4-age categories, as compared with their female counterparts, with exception to alcohol consumption and drug use, which were reportedly higher among girls age 11 and younger, as described in Table 2. Alcohol consumption was the most commonly cited health-compromising behavior (62.4%) with 60.4% of those involved reporting their first drink at or before age 11. Sexual intercourse activity involvement proceeded in order of prevalence (25.1%) with 44.5% of students reporting their first experience at or before age 11 years. In descending order of prevalence were: cigarette smoking (22.5%), drug use (15.7%), and gang involvement (13.5%) amongst all participants surveyed. Involvement in four of the five health risk behaviors, including cigarette smoking, alcohol consumption, sexual intercourse and gang involvement were found to increase with age for both female and male students, ages 12 and older.

Additionally, odds ratios were calculated to describe the relationships between pairs of health-compromising behaviors as stratified by gender. The strongest relationship appreciated, for both females and males, was between drug use and cigarette smoking (OR = 6.37, 95% CI, 3.73, 10.89, OR = 7.90, 95% CI, 5.21, 12.0). The weakest relationships observed were between gang involvement and alcohol consumption (OR= 1.47, 95% CI, 0.873, 2.47) and between gang involvement and sexual activity (OR = 2.16, 95% CI, 1.40, 3.32) for females and males respectively. All odds ratios were statistically significant with exception of the relationship between gang involvement and alcohol consumption amongst female students (see Table 3 and 4).

Table 2. Prevalence of female and male involvement in health-compromising behaviors by age group

Prevalence of Involvement [n, (%)]								
Age	≤ 11		12-13		14-15		16 ≥	
Variable	Female	Male	Female	Male	Female	Male	Female	Male
Cigarette Smoking	0 (0.0)	2 (100.0)	40 (11.9)	43 (23.6)	78 (22.0)	97 (30.7)	32 (38.6)	50 (50.0)
Alcohol Consumption	3 (50.0)	3 (42.9)	160 (47.1)	125 (65.1)	242 (65.9)	250 (72.5)	71 (80.7)	104 (92.0)
Drug Use	3 (33.3)	0 (0.0)	9 (56.3)	25 (73.5)	42 (11.4)	90 (26.1)	20 (22.0)	50 (45.5)
Sexual Intercourse	0 (0.0)	4 (57.1)	20 (6.0)	51 (30.9)	67 (19.6)	141 (48.5)	40 (49.4)	59 (66.3)
Gang Involvement	1 (12.5)	4 (57.1)	22 (6.3)	30 (15.7)	37 (9.8)	61 (17.7)	13 (14.1)	37 (33.9)

Table 3. Association, by odds ratio (95% CI), of health-compromising behavior involvement among Grenadian males attending secondary school

	Cigarette Smoking	Alcohol Consumption	Drug Use	Sexual Intercourse	Gang Involvement
Alcohol Consumption	5.85 (3.42-10.02)	--

Table 6. Association between engaging in sexual intercourse and additional health-compromising behaviors, reported as relative risk (95% CI), among both female and male adolescents

Variable	≤ 11		12-13		14-15		16 ≥		Total	
	Female	Male	Female	Male	Female	Male	Female	Male	Female	Male
Cigarette Smoking	--	--	2.33 (1.02-5.32)	3.03 (1.74-5.26)	2.46 (1.65-3.66)	1.80 (1.22-2.64)	1.58 ^{ns} (0.88-2.84)	0.94 ^{ns} (0.59-1.50)	2.79 (2.08-3.73)	2.00 (1.53-2.62)
Alcohol Consumption	--	1.50 ^{ns} (0.23-9.80)	1.55 (1.13-2.12)	1.27 (1.03-1.56)	1.45 (1.26-1.66)	1.26 (1.09-1.45)	1.31 (1.05-1.65)	1.02 ^{ns} (0.91-1.14)	1.61 (1.45-1.79)	1.26 (1.14-1.39)
Drug Use	--	--	2.22 ^{ns} (0.29-17.19)	2.78 (1.17-6.61)	2.80 (1.42-5.52)	2.06 (1.33-3.17)	3.25 (1.16-9.09)	2.18 (1.09-4.34)	4.25 (2.62-6.91)	2.59 (1.85-3.63)
Gang Involvement	--	--	0.82 ^{ns} (0.12-5.81)	1.66 ^{ns} (0.82-3.35)	1.72 ^{ns} (0.79-3.76)	1.72 (1.02-2.89)	1.79 ^{ns} (0.57-5.66)	1.31 ^{ns} (0.66-2.59)	1.85 (1.08-3.18)	1.85 (1.31-2.61)

^{ns} Not statistically significant, $p > 0.05$.

Also generated were the relative risks of initiation in the defined health-compromising behaviors, provided involvement in alcohol consumption (see Table 5). The strongest relative risk generated for females was between alcohol consumption and cigarette smoking (RR = 4.46 95% CI, 2.84, 6.99) whereas that for males was between alcohol consumption and drug use (RR = 4.18, 95% CI, 2.44, 7.17). Contrarily the weakest associated relative risk, provided alcohol consumption, for females was that of gang involvement (RR = 1.39, 95% CI, 0.86, 2.24), although this was not determined to be statistically significant, and for males was that of sexual intercourse (RR = 1.75, 95% CI, 1.34, 2.31). Additionally examined, were the relative risk values of health-compromising behaviors provided involvement in sexual intercourse activity (see Table 6). The strongest relative risk generated was that of drug use for both females (RR = 4.25, 95% CI, 2.62, 6.91) and males (RR = 2.59, 95% CI, 1.85, 3.63). The weakest proportional risk provided sexual intercourse involvement amongst both females and males, was engagement in alcohol consumption (female RR = 1.61, 95% CI, 1.45, 1.79; male RR = 1.26, 95% CI, 1.14, 1.39).

DISCUSSION

A plethora of studies have been carried out worldwide, which have appraised the clustering of health-compromising behaviors among adolescents [5, 15, 25-29]. However, a paucity of such studies were identified that assessed these factors within the Caribbean country of Grenada.

Amidst a culture where sexual activity and the use of tobacco, alcohol and marijuana are often celebrated [30], Caribbean teens are particularly susceptible to health-compromising behavior engagement. In the present study we examined these very factors amongst Grenadian youth and determined that alcohol consumption (62.4%) followed by sexual intercourse activity (25.1%) and cigarette smoking (22.5%) were the most frequently cited health-compromising behaviors.

The current investigation determined that 59.4% of females and 68.9% of males surveyed reported involvement in alcohol consumption, which, although lower amongst females and higher amongst males, paralleled previous studies by Blum and Ireland, which reported weekly alcohol consumption amongst Caribbean females and males to be 78.7% and 62.1% respectively [31]. With such a high prevalence of alcohol consumption reported, we further investigated the relative risk between engagement in this activity and the remainder of the health-compromising behaviors examined. It was determined that consumption of alcohol rendered both males and females at the highest relative risk for cigarette smoking. Interestingly, we found that sexual intercourse activity was the behavior that most weakly associated with alcohol consumption amongst male students, although it was the second strongest relative risk value calculated amongst female students. When stratified by gender, alcohol consumption was determined to leave individuals at a statistically significantly higher relative risk for engagement in each of the four remaining health-compromising behaviors, with exception of female gang involvement.

In conjuncture with Smikel et al. [32] report on Jamaican adolescent sexual intercourse onset, which determined the mean age of onset among males to be 12.5 years, we observed that 44.5% of sexually active Grenadian adolescents reported their first experience at 11 years of age or younger. This finding supported the findings of Ohene et al. that 82.0% of females and 52.0% of sexually active Caribbean youth reported their first sexual experience at or before the age of 13 years [9]. With current reports citing the Caribbean region as having both the second earliest age of sexual debut and HIV/AIDS prevalence [32] early sexual intercourse engagement is of particular concern to Grenada. As such, we further examined the role of sexual intercourse involvement in overall health-compromising behavior involvement by generation of relative risk values. It was determined that both female and males students were at greatest risk for drug use, provided they were sexually active. When stratified by gender, involvement in sexual intercourse activity was determined to render students at a statistically significantly higher relative risk for engagement in each of the four remaining health-compromising behaviors.

To further investigate the clustering of health-compromising behaviors, odds ratios were calculated. The associations between all pairs of health-compromising behaviors were determined to be statistically significant across both genders, with the exception of gang involvement and alcohol consumption in female students. The clustering of health-compromising behaviors among Grenadian youth is consistent with previous studies carried out both in the region [5] and the world [4, 8, 26, 34] However, these findings are of particular concern among Grenadian adolescents were alcohol consumption and early sexual intercourse debut are the prevailing norm.

The implications of health-compromising behavior initiation, and their clustering, should be cause for serious concern. With adolescents between the ages of 10-24 comprising up to 30% of the population [14] individuals and communities must come to realize that behaviors, which are adopted during the second decade of life, have lasting implications on the well-being of the individual, the community and the public health system [31]. Having established the presence of health-compromising behavior clustering among Grenadian youth, the authors suggest that these findings be utilized to guide future adolescent prevention and intervention programs, which address concurrent health-compromising behavior initiation. Despite the findings documented in this report, additional studies should be carried out to investigate the underlying variables posited for the clustering of such behaviors.

Limitations and Strengths

Limitations worthy of mention include the proceeding factors. As a secondary data analysis, assessments were limited to data obtained from the original study. Furthermore, use of a self-administered questionnaire allows for the possibility of reporter bias. Moreover, as this questionnaire was administered only to Grenadian adolescents attending school it may not be generalizable to all Grenadian youth. Additionally, as a cross-sectional study neither causality or directionality of health-compromising behaviors could be analyzed.

Several strengths were however, evident in this study. As to the best of our knowledge, this is the first study to date, to examine the clustering of health risk behaviors among Grenadian youth. Moreover, information generated from this study may be applied to the development of adolescent public health prevention and intervention programs, which seek to address concurrent involvement in multiple health-compromising behaviors, which is thought to improve upon previous programs which address sets of individual behaviors as opposed to whole persons.

and Anton de Kom University of Surinam,
Paramaribo, Suriname

ABSTRACT

The perception of risk of drug use has been associated with decreased substance use. This study was conducted to determine whether this association applied to university students in Suriname. It also aimed to find out whether academic performance served as a protective factor for drug use. Study design: A Cross-sectional study was conducted that involved male and female undergraduate students between the ages of 18 and 35 years. A randomized cluster sampling was used to select participants attending Anton de Kom University during the 2012-2013 academic years. Students over the age of 35 or below the age of 18 were excluded. Methods: Data was gathered using a survey administered by the Anton de Kom University of Suriname to 250 undergraduate students attending Anton de Kom University in Suriname. Drug consumption patterns, knowledge of consequences of drug use, and academic performance were evaluated using descriptive statistics. Inferential analysis, using correlation ratios (CR), was implemented to determine relationships. Results: Knowledge of consequences of alcohol, cannabis, and cocaine consumption was associated with a decreased tendency to participate in cocaine use (CR = -.23, -.23, and- .20; $p = .01, .01, .03$ respectively). Additionally, cannabis drug involvement was found to be associated with less knowledge of cocaine (CR = -.19; $p = .04$). Conclusion: University students with a less working knowledge of consequences of drug use are at a higher risk of participating in substance use. Therefore, the government

* Corresponding Author's Email: abdoelrahman.sherif@gmail.com.

of Suriname should continue to address substance use and the associated health risks through the integration of such information in both undergraduate and graduate curricula.

Keywords: drug consumption, Suriname, knowledge of consequences

INTRODUCTION

Despite the overwhelming evidence associating substance use with adverse health effects and poor social outcomes, illicit drug use remains a globally recognized problem with significantly increasing prevalence worldwide. According to the World Health Organization's (WHO) World Drug Report of 2012, approximately 3.4 to 6.6 percent of the adult population use illicit drugs such as alcohol, cannabis, and cocaine [1]. As such, the consumption of these drugs contributes appreciably to the global burden of disease. Drug consumption has been linked to poor health outcomes such as psychosis, organ failure, chronic inflammation, addiction and oftentimes death [2-4]. Due to the addictive nature of illicit drugs, users tend to continue abuse until severely ill or dead. In fact, according to the United Nations 1 in every 100 adult deaths are attributed to illicit drug use [1].

In addition to the negative consequences experienced by the individual, productivity losses are of major concern. Society is burdened with the costs of law enforcement, health care, and drug-related crime, i.e., illegal possession, fraud, stealing, and violence [1]. International comparative studies conducted to assess the costs of drug use on society have indicated that the majority of costs are as a result of illness and premature death. For the year 2007, productivity losses in the United States were estimated to be \$120 billion USD (.9 per cent of GDP), decreased labor participation and incarceration being the main causes [1]. This statistic is consistent with global trends, where current prevalence would require an expenditure of \$200-250 billion USD (0.3-0.4 per cent of GDP), to cover global productivity losses associated with illicit drug use and treatment [1]. The impact on national GDP is further exacerbated by the high prevalence of drug use among youth, whom represent the most productive sectors of society and contribute the most to national GDP [1]. Recent studies have also shown an increase in substance use in developing nations, especially those in the Caribbean. According to the United Nations' analysis of the illicit drug market, there are between 10 million-13million drug users in the Caribbean and South America and a 2.8 percent prevalence of cannabis users [1]. This raises major concern because developing nations lack the financial capacity to enforce drug laws and drug prevention programs or cope with drug related productivity losses.

Given the public health and economic concern surrounding substance use, attempts have been made on both national and international levels to discourage drug use worldwide. However, the multifaceted etiology of substance use makes it difficult to address. Fortunately, despite its complicated nature, research findings substantiate the notion that beliefs and attitudes regarding drug use, mainly the knowledge of the consequences (KOC) of drug use, influence the likelihood of engaging in substance use. Therefore, lack of KOC of drug use (or low perception of risk) may be associated with the high prevalence of drug use in the Caribbean and can be targeted as a point of intervention.

Bejarano conducted a study examining the perception of risk and drug use in six Latin countries through a survey distributed to high school students [5]. The perception of risk is a

cognitive process in which individuals allocate certain attributes, positive or negative, to a behavior; in this case, drug use [5]. The questionnaire asked respondents to identify the level of risk associated with particular consumption patterns. Results revealed that an average of 16.7% and 22.7% perceived risk were associated with cocaine and marijuana, respectively [5]. Low perception of risk was found among those more likely to use substances. However the question remains whether academic performance, or overall cognitive capacity, (possibly associated with KOC of drug use) is correlated with decreased drug use as well.

Currently, there is no information available for the Caribbean region, even less in Suriname, about the possible correlation between knowledge of consequences, academic performance, and substance use. It is important that such associations be assessed in this population in order to inform drug prevention programs in Suriname as it is becoming a growing concern. Therefore, the objective of this study was to examine the relationships that exist between perceived risks, drug use, and academic performance in Suriname. The purpose of this study was to provide government of Suriname with an assessment of the influence that academic performance and knowledge of consequences of drug use may have on drug use among university students in Suriname. This was accomplished through a secondary data analysis of the survey conducted in Suriname in order to address the following objectives: to determine association between knowledge of consequences of drug use and drug consumption among university students in Suriname and to determine association between academic performance and drug consumption among university students in Suriname.

METHODS

The Inter-American Drug Abuse Control Commission's (CICAD) International Drug Research Capacity-Building Program's cross-sectional study in Suriname involved a target population comprised of undergraduate students between the ages of 18 and 35 years. Randomized cluster sampling was used to select approximately 250 undergraduate students attending Anton de Kom University during the 2012-2013 academic years. Students over the age of 35 or below the age of 18 were excluded. Students were informed of the purpose of the survey and given an informed consent with information regarding procedural instructions, eligibility, risks, benefits, confidentiality, and contact information. All students who provided informed consent were given 20-30 minutes to complete the questionnaire. Students were allowed to discontinue participation at any time. The survey included questions addressing, socio-demographic information, and knowledge about consequences of drug use, academic performance, and drug consumption patterns. Refer to Appendix A for survey questions and additional information on sampling. The primary independent variables were KOC and academic performance. KOC was defined as the knowledge students had regarding the negative biological, psychological and social outcomes associated with the use of cannabis, alcohol, or cocaine. For each drug, correct answers corresponding to true or false statements were given the value of 1. Incorrect answers received a score of 0. Total knowledge scores ranged from 0 to 14 for each drug and the highest scores signified more knowledge. Academic performance was a number selected (by the student) to represent the student's perceived level of academic performance with classification as either low (1-3), average (4-

6), or high (7-10). The dependent variable, drug consumption (yes or no), was defined as the use and/or abuse of alcohol, cannabis, or cocaine.

Table 1. Summary of participant demographics (n = 250)

	n (%)
Gender	
Male	70 (28)
Female	180 (72)

Second	38 (15.2)
Third	7 (2.8)
>=Fourth	5 (2.0)

The survey was conducted with the approval of the research Ethics Board of the Center of Addiction and Mental Health (CAMH) and the Board of Directors of the Anton de Kom University of Suriname.

Frequency and percentage distributions were determined to assess the prevalence of drug consumption, the distribution of knowledge scores, and academic performance levels. A correlation analysis was conducted to explore the relationship between these variables.

RESULTS

During the 2012-2013 academic year, 250 students participated in the study. The average age was 21.5 years, 180 (72%) were women, 222 (88.8%) studied social sciences and lived at home, and 200 (80%) were in their first year of study. Additional sociodemographic characteristics are shown in Table 1. When measuring the prevalence of drug use at the university in the past 12 months, alcohol was the most prevalent (62%) at the university, followed by cannabis (6.2%). Cocaine use was not seen however there was a minor increase in prevalence (1.8%) when examining lifetime drug use. Approximately 77% of the students have used alcohol and 11% cannabis in their lifetime. Problematic drug involvement was measured by using the ASSIST substance specific involvement approach to quantify

consumption patterns as described in appendix A. Approximately 11.2% of the students are at-risk for problematic alcohol involvement, 6.4% cannabis, and less than 1% for cocaine use.

Table 2 presents the correlation coefficients between knowledge of consequences, drug consumption and academic performance. Though significant, the correlations between cocaine drug involvement with knowledge of consequences for alcohol, cannabis and cocaine were weak, -.23, -.23, -.20, respectively ($p = .01, .01$, and $.03$). Cannabis drug involvement and knowledge of cocaine presented a minimally significant correlation as well of $-.19$ ($p = .04$). The relationships between knowledge of consequences had moderate relationships with each other, indicating that an increase in knowledge with one drug corresponded to an increase in knowledge with the other drugs.

Difference in the knowledge of cannabis and cocaine by students who consume cannabis and those who do not were statistically significant ($p < .05$) (see Table 3). On average, students consuming cannabis had a lower KOC score for cannabis (mean 10.41, s.d. 2.68) than those who did not (mean 11.48, s.d. 1.58). A similar trend was seen with the knowledge of consequences for cocaine. On average students who consumed cannabis had a lower KOC score for cocaine (mean 10.31, s.d. 2.14) than students who did not use cannabis (mean 11.62, s.d. 1.61). All other differences were statistically insignificant. There were no statistically significant differences in academic performance and drug use or in KOC scores and alcohol consumption (see Table 2).

Table 2. Correlations between knowledge of consequences, drug consumption and academic performance

	KOC: Alcohol	KOC: Cannabis	KOC: Cocaine
KOC: Alcohol	--	.400**	.306**
KOC: Cannabis		--	.461**
KOC: Cocaine			--
DI: Alcohol	-.028	-.119	-.097

Academic Performance	.565	.578	.168

Note: ** Correlation is significant at the 0.01 level (2-tailed), * Correlation is significant at the 0.05 level (2-tailed).

Table 3. Comparison of average knowledge of consequences and cannabis use

	12-month cannabis consumption	N	KOC Ave. (sd)	t-test
KOC Alcohol	No	182	11.78 (1.59)	-1.81
	Yes	14	12.57 (1.45)	
KOC Cannabis	No	176	11.48 (1.58)	1.36 *
	Yes	12	10.41 (2.68)	
KOC Cocaine	No	172	11.62 (1.61)	2.78**
	Yes	13	10.31 (2.14)	

Note: ** Correlation is significant at the 0.01 level (2-tailed), * Correlation is significant at the 0.05 level (2-tailed).

Table 4. Consequences of past three months use: Alcohol

	Never	Once or Twice	Monthly	Weekly	Daily or almost Daily
	n (%)	n (%)	n (%)	n (%)	n (%)
Strong desire	95 (38)	80 (32)	13 (5.2)	17 (6.8)	5 (2)
Problems	96 (78.4)	11 (4.4)	0	1 (0.4)	0
Failed normally expected	191 (76.4)	12 (4.8)	0	1 (0.4)	0

DISCUSSION

Overall the data showed that knowledge of consequences (KOC) of drug use is associated, though minimally, to decrease in drug involvement. On average students consuming cannabis and cocaine displayed a lower knowledge of consequences of cannabis and cocaine. Thus suggesting that students using these drugs do so because they are unaware of the negative effects of consuming cannabis and cocaine. As stated before, a negative correlation was found between cocaine drug consumption and knowledge of consequences of alcohol, cannabis and cocaine indicating that increased knowledge of consequences of either drug was associated with a decreased tendency to participate in cocaine use. In addition, cannabis drug involvement was associated with less knowledge of cocaine ($r = -.19$). This coupled with the finding that increased knowledge with one drug coincides with increased knowledge with another suggests that efforts aimed at drug prevention should provide information concerning the consequences of using various drugs in order to discourage them from participating in substance use of all types, rather than just alcohol.

Unfortunately, a significant percentage of students answered incorrectly when asked to identify true statements regarding consequences of alcohol, cannabis, and cocaine use (avg. = 18.05%, 19.43%, 17.6% respectively). Misconceptions among students included beliefs that consuming alcohol, cannabis, or cocaine may result in improved muscular strength, expansion of one's mental capacity, and improvement of romantic relationships. Therefore, continued use of these drugs, regardless of the student's knowledge or experience of the consequences, may be attributed to incorrect perceived benefits. For instance, of those who have consumed alcohol in the past three months, a significant amount had a strong desire or urge to use alcohol once or twice (see Table 4), despite the fact that they experienced health, social, legal or financial problems and/or were unable to achieve what was normally expected of them. A similar pattern was seen with both cannabis and cocaine. Fortunately very few students expressed failure to control substance use at any given point in time.

Although the association between KOC of drug use and drug use itself is minimal, it exists and provides support for the implementation of a education-oriented drug prevention program in Suriname. Due to the correlation found between the increase in knowledge with one drug to another and the overwhelming use of alcohol (compared to cannabis and cocaine) among the university students, the governments drug prevention program should incorporate information about the consequences of using different types of drugs with an emphasis on alcohol. Also, the lack of correlation between academic performance and drug use suggest that the students' academic performance (avg. = 6.3) was not an indicator of the "type of student" who would participate in drug use. Students, whether performing well in school or not, are at risk and can benefit from information concerning the consumption of cannabis, alcohol, and cocaine.

Furthermore, additional research should be done to explore other underlying reasons of drug use such as age, gender, or familial dynamics. Very few students indicated that they've had a friend or relative express concern about their use of alcohol, cannabis and cocaine. This is surprising given the fact that 11.2% of the students are at-risk for problematic alcohol involvement. The program can therefore provide information to the families of students about the consequences of drug use in order to increase the perceived risk of drug use within communities in Suriname. However, further research should be conducted to examine the

degree of influence family and friends have, if any, on the choice students make to participate in such risky social behavior.

Because the majority of the students displayed working KOC of drug use, one goal of the program should be to focus on increasing the students' perceived vulnerability to experiencing those negative consequences. Thus far, Suriname's National Drug Master Plan supports efforts towards supply reduction, demand reduction, and control measures. Suriname has also ratified various bilateral anti-drug agreements with neighboring countries such as Guyana, Brazil, Venezuela and Columbia. The fight against drugs has primarily been the responsibility of the Narcotics Squad of the Suriname Police Corps and Customs and the Military Police Corps [7]. More resources are being allocated towards drug-law reinforcement as opposed to educational approaches for drug prevention. However, based on the evidence gathered, drug prevention through the introduction of curricula covering drug use, consequences, and related content in both undergraduate and graduate programs should also be the government's main focus.

ABSTRACT

The health of an individual is inherently intertwined with the elements of the environment and the community in which the individual lives. However, improving health and wellbeing at the community level is fraught with challenges. After framing social and community dimensions of health, we highlight four cases of personal involvement by the authors focused on varying approaches and lessons learned regarding community engagement in the pursuit of improved health conditions. Two cases highlight

* Corresponding Author's Email: lrubi01@emory.edu.

successful project interactions and insights, but problems with long-term sustainability. Two other cases show the value of sustained resources, infrastructure, and relationships between researchers and community partners. Key components of community partnerships and engagement are offered to inform successful health promotion efforts.

Keywords: public health, community, environment, partnership

INTRODUCTION

This paper is a product of a symposium held during the 11th Annual Break the Cycle Conference in Atlanta Georgia April 2016. Jasmine Williams, a student in the Department of Veterinary Science and Public Health, Fort Valley State University, Fort Valley, Georgia, participated in our 10th Annual Break the Cycle program by focusing on indoor triggers of asthma in children in the town of Fort Valley Georgia [1]. Fort Valley is a small, poor town of about 10,000 people, 80% of whom are African American, with a low literacy rate and limited resources. It is prototypic of the segregated towns that are relics of the shameful history of slavery and racism that was a part of the character of the US South: a town lost in time. This student planned to look at the relationship between the conditions of the houses in the town as factors in the prevalence of asthma among the children. What she found was a complex sociological study of a group of people in an almost intractable situation where poverty and lack of education perpetuate the cycle of environmental health disparities.

In order to carry out her project, she proposed a partnership involving community leaders, as well as medical, environmental, and public health professionals to create a forum to promote asthma awareness and empower members of the community to address the factors that are responsible for the high prevalence of asthma. In addition, she proposed raising funds and support to renovate housing units which were in a dilapidated state, and to provide more community based health literacy training.

The response of the community to her invitations to participate in her project was minimal, despite incentives. Indeed, the prevailing sentiment reflected one of distrust and a sense of resignation that had developed in the community over many years of neglect and failed promises as well as a fear that someone would want something from them and would take away what little they had – in terms of both material possessions and dignity. Although she was only able to open the lid of Pandora's Box, she also opened the door to explore ways to make a difference and break the cycle to improve the health and well-being of the children.

As a response to this challenge we organized a symposium on "Community engagement" at our 11th Annual Break the Cycle conference with a set of formal presentations and a workshop for the attendees to take on the challenge. The lessons learned from the exercise gave us additional insights into the issues of working with a community – generally poor, underserved and, to a significant degree disenfranchised – to help improve the health of the individuals in their community and, hence the health of the community as a whole. Although this is a noble sentiment it is by no means simple.

A community beset by adverse social, economic and environmental factors may be desperate for change for the better, but this is by no means a simple task. Often, communities such as these consist of many people in differing circumstances at different levels in society, and with many different and sometimes competing interests and agendas. Often, they have

had interactions with organizations and institutions of authority, whether government or private, that have left them disappointed and with failed hopes, therefore reluctant to let strangers in again. The challenge we set for ourselves was: how do we approach this community, how do we overcome their fears and suspicions that have been caused by previous negative experiences, and how do we make a difference by creating a collaborative partnership of trust and mutual respect to enable them to make a difference and become proud of who they are and where they live.

In this paper we will explore the concept of Community Engagement and provide examples of community engagement projects and programs that will illustrate some of the scope of the field as well as the successes and failures that can be associated with the activity.

HEALTH

World Health Organization (WHO) defines health as follows: “Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity” [2]. This definition has not been amended since 1948. Individual health and wellbeing are associated with a state of existence that encompasses a level of satisfaction with a sense of security, a physical ability to go where you need and do what you want, and a freedom to pursue happiness with your fellow human beings in your community and, if you wish, and are able, in the broader world. This is not a static situation, because the passage of time and circumstances generate constant challenges requiring active engagement to resist perturbations. Continually striving to overcome the challenges may result in moments of satisfaction and happiness. The health of an individual is inherently intertwined with the elements of the environment and the community in which the individual lives. The health, happiness, and wellbeing of each individual are part of the health, happiness, and well-being of the community and represent an ecological homeostasis.

HEALTH DISPARITIES

Healthy People 2020 characterizes health disparities as health differences that are closely linked with social, economic, and/or environmental disadvantage [3]. Health disparities adversely affect groups of people who have systematically experienced greater obstacles to health based on their socioeconomic status, racial or ethnic group, age; gender, religion, mental health, cognitive, sensory, or physical disability, sexual orientation or gender identity, geographic location, or other characteristics historically linked to discrimination or exclusion. These factors collectively predispose to adverse health outcomes as well as to limited access to quality healthcare, thus further exacerbating the health disparities [3].

SOCIAL DETERMINANTS OF HEALTH

The social determinants of health are the circumstances in which people are born, grow up, live, work, and age, as well as the systems in place to educate children, to provide safety

and security for the citizens, to provide means of safe transportation and to provide services to promote health and to prevent and treat health related conditions [4]. Social determinants of health are shaped by the distribution of money, power, and resources throughout local communities, nations, and the world [5]. These are the factors that contribute to health disparities.

The World Health Organization further defines social determinants of health as: a complex, integrated, and overlapping set of social structures and economic systems that are responsible for most health inequities. The WHO focused on the social determinants of health as a means to achieve global health equity by the articulation of a set of “Millennium development goals” (MDG 2015) [6] which represent the factors include eradication of poverty and hunger, universal primary education, gender equality, reduction of child mortality, improvement in maternal health, combating infectious diseases, ensuring environmental sustainability, and building global partnerships for development. Although these eight goals have since been supplanted by the 17 of the “Sustainable development goals for 2030” (SDG 2030) [7], they continue represent a core of concerns that affect the health and well-being of people across the world in in our global collective society.

HEALTH OF COMMUNITIES

A community can be seen as a collection of people who live and interact together as a group. This larger conceptualization considers the community as a number of individuals tied together by place and common characteristics, heritage, interests, and culture. In some cases, persons in a community may be tied more by common interests than by shared space place, given the current ease of communication and transportation across geographical space. As such, a healthy community is one in which all residents or group members have access to a quality education, safe and healthy homes, gainful employment, transportation, physical activity, and nutrition, in addition to quality health care.

Figure 1. Ecological framework of health.

Communities are collectively the building blocks of the society and the country in which they are located. The population health status of a country and factors that have the potential to influence health outcomes, such as health care access and quality, health behaviors, social factors and the physical environment are critically dependent on the political framework of the country, the economy, as well as the culture and social fabric of the society. Figure 1 represents such an ecological framework. Although the diagram appears 'nested' the elements need to be seen in a more dynamic, interactive manner that reflects reality in its many fluid dimensions.

APPROACHING THE HEALTH OF A COMMUNITY

When approaching the health of a community it might be helpful to frame the discussion in terms of an individual health encounter. The relationship and the intent are similar but the framework is different and the situation is far more complex. In the situation of a personal health encounter, an individual with an ailment is likely to seek out a health care professional who will diagnose the problem and offer a treatment plan. The process involves a face to face visit during which the 'patient' states what the symptoms are and the health care provider asks further questions that try to identify the cause and the diagnosis, performs a physical examination and may order relevant laboratory studies to establish a diagnosis and then to develop a treatment plan. This model can be readily adapted to the situation of a public health concern. The community raises a concern about the health of its community members; the public health team responds with further investigation into the nature of the situation, including the cause and its effects and then develops a plan of action for the community that may involve additional resources and strategies. The similarity between the two scenarios is valid, but clearly the public health concern involving a community has a greater degree of complexity and requires a greater degree of planning and organization to develop the plans of action and solicit active participation of the community in question to follow through with the recommendations. Lessons from the direct healthcare provider-patient care model are instructive. For example, we have learned that the active participation of the patient in the diagnostic and therapeutic process results in a better short-term and long-term set of outcomes [8].

There is substantial evidence that strategies for informing and empowering patients and involving them in their health and health care has a positive impact on health outcomes. Health literacy on the part of the patient plays a large role in this process and contributes to decision-making in the management of health related conditions. WHO stresses that, when patients have to make important health decisions that affect health outcomes for health concerns, especially for chronic health conditions, informing and empowering patients about health and healthcare enhances the health outcomes and ensures the future sustainability of health systems. WHO offers a number of strategies that include written and electronic information sharing, as well as education programs for physicians and their patients [8].

The application of this model in the relationship between a public health organization and the members of an affected community can be critical to the success of the intervention. This latter process can be referred to as community engagement.

COMMUNITY ENGAGEMENT

Community engagement is a relatively flexible term that can be characterized as a process of working collaboratively with and through groups of people affiliated by geographic proximity, special interest, or similar situations, to address issues affecting the well-being of those people [9]. The process involves building authentic partnerships, with mutual respect and active, inclusive participation; and power sharing and equity; towards mutual benefit. In general, the goals of community engagement are:

- to build trust,
- enlist new resources and allies,
- create positive patterns of communication, and
- improve overall health outcomes as successful projects evolve into lasting collaborations

CASE DISCUSSIONS

We present four case scenarios, in which the authors had personal involvement; each is different in its focus and intent, but the similarities are in the desire to improve the health of the members of the target communities. The process in each was dependent on the community in question, the particular health-related issue raised and the relationship that developed between the particular individuals and organizations initiating the interaction and the members of the community – the leaders, the stakeholders and the general citizenry.

In the following set of examples we will explore the elements of the particular issues and the process and then review the literature on the process of community engagement which offers suggestions to assure a greater likelihood of a positive outcome in terms of the health of the community and the sustainability of the community in terms of the strategies adopted by the community to maintain good health and have tools at their disposal to deal with related health issues in the future.

Case Study: Anniston, Alabama [10]

In the year 2000, the city of Anniston, Alabama was embroiled in a situation in which segments of the community were exposed to high levels of polychlorinated biphenyls (PCBs), which are by-products of the chemical industry and are known to have adverse health effects including acne-like skin conditions in adults and neurobehavioral and immunological changes in children as well as causing cancer in animals [11]. These chemicals had been produced in large quantities and were dumped into landfills, subsequently seeping into the water table and resulting in highly toxic levels in local rivers and in the fish in these waters. The resulting diseases and death of the fish alerted the Centers for Disease Control Agency (CDC) and the Agency for Toxic Substance and Disease Registry (ATSDR) to the presence of the toxin. In February 2000, CDC and ATSDR released a “Health consultation on the evaluation of soil, blood and air data from Anniston, Alabama” that summarized data available to that point.

The analysis showed widespread PCB-affected soil in Anniston, which posed a serious public health hazard [12]. Blood testing confirmed a pattern of human PCB exposure that identified Anniston as one of the most heavily exposed communities in the nation. These levels were much higher than the mean serum PCB levels of 0.9 to 1.5 ppb found in recent years in unexposed populations.

Community Reaction

Obviously when the news of this contamination became public, the affected citizens were distressed and wanted to be rid of the toxins in the environment and in their bodies. The reality of the situation was that the people most affected by the presence of the PCB's were the poorer members of the community who also happened to be African American. These residents worked in the factories, lived nearby, and were sometimes provided with soil contaminated with PCB's to use on their fence posts to prevent termites. A further complication occurred in that the factories, realizing that they were responsible for the contamination and the toxicity causing serious health related consequences, closed their operation and moved out of town. Although this resolved part of the problem by eliminating the further production of PCB's, it created massive job loss and eroded the tax base that had been the engine of the local economy. As a result, not only were the citizens of the community in West Alabama still contaminated by the remaining PCB's, they were plunged into a situation of greater unemployment, poverty, and anger. A number of community activists arose to form advocacy groups who sued the chemical company.

It was during this situation that the Southeast Pediatric Environmental Health Specialty Unit (PEHSU) based at Emory University in Atlanta was asked by the Region 4 Environmental Protection Agency (EPA) Office to provide information and guidance to the pediatric community in Anniston to help them deal with the concerns of the parents about the health of their children as a result of PCB exposure. PEHSU's had been established in 1998 through a joint agreement by EPA and ATSDR to provide an interconnected system of specialists located throughout North America, corresponding and related to the EPA regions, to respond to questions from public health professionals, clinicians, policy makers, and the public about the impacts of environmental factors on the health of children and reproductive-age adults [13]. Thus the Southeast PEHSU was tasked with responding to the environmental health situation in Anniston Alabama.

The original scope of that request focused on providing Continuing Medical Education (CME) sessions for Anniston physicians. Through this process, representatives of the Southeast PEHSU met concerned physicians and learned from them about existing programs for children and other community resources. Once in the community it became clear to PEHSU physicians that merely providing information about the chemical and its toxicity was not enough to make a difference. The situation in Anniston was much more complex than merely the toxic effects of the PCB's; it was a mix of psychological, social, economic and political elements that were difficult to disentangle and resulted in a fractious relationship between the predominantly African American community in West Anniston who were directly affected by the toxins and the economic fallout of the factories leaving town and the members of the predominantly white community on the other side of the tracks who were not

directly affected by the toxins but shared economic loss from factories leaving the area. In addition, they experienced an economic impact from the negative publicity about community health conditions.

This fractious situation was at an impasse; clearly a mere delivery of CME lectures to the pediatricians of the town was not going to make much difference. Fortunately, the support from the Region 4 EPA enabled the Southeast PEHSU to become more involved in the community. Over the course of two years PEHSU staff were able to create a viable and functioning steering committee which consisted of representatives from the different community stakeholders, including the mayor, as well as representatives from the business community, the pediatric community, the school system, the early intervention programs, leadership from the activist community and parent organizations. This steering committee met on a monthly basis to explore ways to overcome the dark cloud of toxicity and division within the community and to work together to promote the health and wellbeing of the children of Anniston. To this end the group held two community Health Fairs and ultimately, in 2002, helped to create a private not-for-profit organization called *Vision 2020: For the children of Anniston*, which had as its mission to assure that by the year 2020 all children in Anniston would graduate from high school. This meant that the children born in that year would be the beneficiaries of this organization.

Unfortunately, the funding for the Southeast PEHSU to work with the community came to an end and so did the carefully cultivated community relationship with PEHSU. The lawsuit against the chemical company was successful, but the plaintiffs received a pittance of the millions of dollars in awards and became further disenchanted. Vision 2020 was disbanded, and the community has returned to a new/old equilibrium – now almost at the time when the vision of Vision 2020 would be realized. A brief moment of success – a mere taste – like footprints in the sand on the beach – was erased with the tide.

What did we accomplish? Did we indeed make a difference? And, did we make a difference for the people of Anniston or only briefly for those who participated in the steering committee?

At PEHSU, we are continuing to take lessons from that experience and to translate it into new challenges and to continue to try to make a difference in the lives of those who endure adverse social, economic and environmental factors. In particular, we have learned that resources must be invested for an indeterminate time in order to make a difference in complex community issues. Whether those resources are externally or internally generated, they must be sustainable in order to realize a long-term plan. One outcome was the partnership between the Southeast PEHSU and a not-for-profit organization, Innovative Solutions for Disadvantage and Disability to develop the Break the Cycle of Environmental Health Disparities Program, which recently received an award from the US Environmental Protection Agency for promoting children's environmental health.

Case Study: Alaska

The incidence of diabetes among Alaska Native people is high. A 2007-2011 research project funded by the US EPA sought to investigate the health properties of wild Alaska berries and the role they play in traditional Alaska Native community life and knowledge that

might help mitigate health risks [14, 15]. Youth aged 5 to 18 years from three study communities (Akutan, Seldovia, and Point Hope) were engaged as research partners. They helped conduct interviews and surveys with community members, as well as field assays of wild berries. Beyond these important research roles, however, these young people, particularly in Point Hope, changed a researcher's mental model of community vulnerability forever.

Literature on social and environmental conditions in Alaska is full of examples of risk assessments. From every angle, it seems there are hazards and vulnerabilities threatening the wellbeing of people and nature. Alaska's far northern position increases the impacts of climate change and related stresses on natural resources and subsistence foods. Legacies of environmental contamination as well as threats from ongoing and planned resource extraction pose myriad problems. Health and behavioral health conditions and risks pose particular challenges for Alaska Native people and are exacerbated by the loss of traditional knowledge and practices. Based on this background information, the researchers went into the three study communities with a focus on risk, hazard, and vulnerability. The line of questioning often started with, "What threatens your community?"

Working with young people is a remarkable experience. Their diverse personalities are less shielded than adults and, often, they are less inhibited in communicating what they are thinking and feeling. This was the case in Point Hope, Alaska. During our second visit, one young woman spoke up during a group discussion and said, "I don't want to do this anymore. It's all so depressing. Why are you only asking us what's wrong with us? How come you never ask us what's good about our village and our land and our sea?" Needless to say, that was a pivotal moment for the sociologist on the project who from that moment on expanded the focus of her work to encompass wellbeing, rather than just risk and risk perception in changing environments. With the help of the young people in Point Hope, the study shifted to investigating quality of life and wellbeing as well as factors posing threats to community residents and the natural environment.

Empirical investigation yielded insights into how Point Hope's youth saw their future as compared to adults. While they shared adults' appreciation for how traditions were honored and how people supported each other, young people were more likely to articulate concerns about the safety and cleanliness of their environment and too few opportunities to be involved in local governance. They created long lists of things they liked best about their community and place and the benefits of living there, including freedom, abundant food from nature, hunting and whaling, fun outside in nature with family and friends, and longstanding traditions. It wasn't that they didn't speak of threats. They did. They indicated concerns about drugs and alcohol and loss of traditions, of the threat of oil drilling and possible spills and other contamination, and of climate change threatening their relationship with sea and ice and wildlife. As they learned from the research project about the health benefits of their wild berries, they simultaneously taught the researchers that studying environmental health is as much about assessing abundance and quality as it is about threats and risks. Furthermore, they showed the value of engaging a community, and its youth in particular, in order to move beyond vulnerability to promote a cycle of environmental health capacity that includes learning, fun and play, healthy food, community traditions, and time in nature.

Alas, the project ended as the funding ended. There is no ongoing relationship between the researchers and the people of these communities. Not only have we no way of tracking whether the project made any lasting impact on the lives and health of these people, but also

the ongoing local insights and experiences no longer have a conduit to informing scientific understanding. The longer-term sustainability of community empowerment and of relationships between local communities and researchers must be a higher priority in the realm of environmental health.

Case Study: The Georgia School-Based Health Center Project

PARTNERS for Equity in Child and Adolescent Health in the Department of Pediatrics at Emory University School of Medicine was developed to enhance the health and well-being of the underserved children and adolescents in the state of Georgia [16]. The purpose of PARTNERS is to increase access to quality health care, improve the delivery of health services and improve the overall health of the children of Georgia. The components and mission of PARTNERS includes: expansion of school based health clinics (SBHC) throughout the state; increased access and improved delivery of primary care services for underserved populations; improved academic outcomes through the development of innovative programs that link healthcare, education and community services; and the training of future pediatricians and other medical providers to provide medical care that addresses the social determinants of health. The vision of the program is to reduce health disparities ensuring that all Georgia children are more likely to be happy, healthy and productive members of society.

Twenty-eight million children nationwide come from economically disadvantaged households and are at risk for a variety of negative outcomes including 1) increased rates of health problems and mortality, and 2) increased risk of academic underachievement and school drop-out. School-based health centers (SBHCs) are safety net health organizations that increase access to healthcare and improve academic achievement for underserved students [17]. SBHCs were first introduced in late 1960s (Cambridge, Massachusetts) and early 1970s (Dallas, Texas and St. Paul Minnesota) to provide affordable and accessible healthcare for poor children and adolescents [18]. There is significant evidence in the literature to support the role of SBHCs in increasing access to healthcare, improving health outcomes and reducing health disparities (i.e., mental health, asthma) and reducing medical costs for the most needy children and adolescents in our nation [19].

There are approximately 2,400 SBHCs nationally, which reflects a four-fold increase within the past 20 years [20]. Less than 1% of public elementary schools house SBHCs despite strong evidence of effectiveness from model programs. Four issues must be addressed in taking SBHCs to scale: evidence of community need and support, sustainability, evidence of health and health cost impact, and fidelity to exemplar models [21].

Following an exemplar model (Whitefoord Elementary School-Based Health Center in Atlanta, Georgia) [22] and under the direction of PARTNERS for Equity in Child and Adolescent Health of the Department of Pediatrics at Emory University, the Georgia SBHC Project was created to expand SBHCs in Georgia with 3 phases – planning, implementation, and sustainability. One-year planning grants were awarded beginning in 2010 to Georgia counties for local stakeholders to provide evidence of community need and support. The purpose of the planning grants was to increase knowledge and public will around the development of SBHCs. Grantees were required to create a community advisory group

consisting of stakeholders in child and adolescent health and education. Members included representatives from the school system, health care providers, community agencies, parents, local politicians and child advocates. The planning grants included the following activities:

- **GRANTEES PARTICIPATED IN:**
 - developing a community advisory group to work towards accomplishing the goals of the grant,
 - conducting a needs assessment to define the health and academic need of students,
 - defining strategies to address needs,
 - identifying specific school(s) for clinic services, and
 - developing a business plan for establishing the SBHC.
- **PARTNERS:**
 - conducted three SBHC workshops at Emory with the assistance of staff from the national School-Based Health Alliance
 - held monthly conference calls to provide technical assistance, address challenges, celebrate successes, lend encouragement, and
 - conducted site visits and presentations to members of advisory groups and community leaders to educate and provide a forum for addressing concerns of the community.

Over the past six years, PARTNERS has awarded planning grants to 37 counties representing 41 communities throughout Georgia. Central to the planning process was the alignment of the resources, talents, and organizational vision of each stakeholder. Another critical element was the work of a SBHC champion who was vital in minimizing mission creep and in keeping the process going when faced with challenges within and without the advisory council (i.e., key member turn-over, opposition from medical providers, etc.). Called upon to define the needs of its children and to develop strategies to address these needs, each advisory council participated in conducting a needs assessment using primary and secondary data. Primary data collection was obtained through focus groups, key informant interviews and surveys of parents, teachers, school administrators and community leaders. Information obtained included knowledge of SBHCs, health (physical, psychosocial, oral) needs of students, barriers to access to medical providers, need for a SBHC, and likelihood of using or referring students to a SBHC. School system, state and county sources were used for secondary data collection. School achievement, absenteeism, percentage of children living in poverty, overall health status of children in the county as compared to the state, resources available to address the health and academic challenge for students were elements of the secondary data collection.

Using the data, the council was charged with developing specific strategies to address the needs through the creation of a SBHC. The strategies included:

- Which school would be best served by a SBHC
- What services should be offered by the SBHC
- What medical entity would serve as the medical sponsor of the SBHC
- What community resources were available to support the SBHC; and
- How to obtain funding for SBHC start-up.

As a result of these community grants, the number of SBHCs in Georgia has increased from two to 22 over the past 5 years. These are comprehensive, full-service SBHCs that provide primary health care to students and staff and, for some, both behavioral and oral health as well as primary care. These 22 SBHCs can potentially impact the health and well-being of approximately 11,000 students. Several other communities are poised to begin when funding is secured and continue to meet as an advisory council well beyond the planning process. In addition, other communities involved in the planning process that were not able to develop a comprehensive school based health center chose to expand existing school health programs using telemedicine or by adding behavioral health services alone. There are currently over 80 schools with telehealth and three with just behavioral health programs.

We have demonstrated the importance of community buy-in and support in expanding SBHCs throughout the state. Galvanizing community stake-holders around defining and addressing the needs of its children is key not only for planning but also for implementing and sustaining these centers as well.

Case Study: Community Engagement Adds Value to Environmental Health Science

When environmental health (EH) research omits community knowledge, it can lead to research results that are not easily translatable into actionable information for the public. In other words, community engagement can improve the relevance and benefits of EH research. Community-engagement in EH research lies on a continuum from outreach to collaborative research partnerships with shared leadership between the scientists and community. Ideally, in a collaborative EH research partnership, the community identifies an environmental exposure concern and participates in the translation of that concern into a research question and then into the design of a research study. Ultimately, the community partner may take a lead role in the use, translation, and dissemination of the research findings.

Of course, environmental exposures do not happen in isolation from the other determinants of health, as there are many influences on human health from genetic inheritance to economic factors. The Exposome is a new approach to better consider these multiple influences, including environmental exposures, into the study of human health. In simplistic terms, the Exposome is everything that influences health throughout a lifetime except the inherited characteristics with which we are born. Importantly, because Exposome science is an emerging approach, it represents a unique opportunity for community input into science at an early stage. The integration of community knowledge should be a key component of the newly developing Exposome science and is a primary aim of the HERCULES Exposome Research Center at Emory University in Atlanta, Georgia [23].

In order to engage the Atlanta community in the new Exposome approach to science, HERCULES needed to start where the community is and learn both the environmental health concerns of the local community and what other factors are priorities to the community. Before going into the community, HERCULES reached out to community leaders and stakeholders active in Atlanta's environmental health network. Many of these individuals agreed to serve on a stakeholder advisory board (SAB) not only to provide input into the scientific activities of the HERCULES center, but also to guide the center in its community

engagement efforts. The SAB emphasized the importance of bringing immediate benefits to the community-- in the form of knowledge, capacity building, resources, and partnerships – all components essential to community empowerment and the sustainability of community-led efforts to address local EH concerns.

Building trusting relationships with the community takes time. Part of that trust is supporting the community in their efforts to address local concerns. For HERCULES, this includes sharing both financial resources and expertise in the Clarence “Shaheed” DuBois Community Grant Program [24]. This program provides funding and technical assistance to organizations that aim to conduct outreach, to promote community awareness of local environmental health concerns, or to collect information needed to address local environmental health concerns. This program funds 4-5 community projects per year. Funded projects have ranged from an educational campaign to educate refugee parents about the health impacts of cigarette smoking indoors to urban agricultural gardens teaching local residents the skills to grow and cook their own healthy foods. An evaluation of the community grant program is currently being conducted in which four dimensions of community capacity are being examined: knowledge and skills, leadership opportunities, partnerships, and resources leveraged. Preliminary analyses of qualitative interviews with grantees suggest the community grants were successful in strengthening several dimensions of capacity.

As articulated above, the purpose of community-engaged EH research is to conduct research that is relevant to the community and produces scientific findings that can be translated into actionable information that improves overall health outcomes. The relationship building with both SAB members and in the community lays the foundation for the conversations and interactions between researchers and community members that may lead to research partnerships. As part of this process, HERCULES researchers participate in community-organized meetings focused on local environmental challenges. Two community-driven scientific projects have emerged from researchers being present in the community and learning of local concerns. Both of the projects were funded through a competitive pilot program offered to scientific faculty associated with HERCULES. The funding for both projects was shared between the community partnering organization and the scientific team, and community residents served as citizen scientists in both projects. The first project entailed a health survey in two impoverished Atlanta neighborhoods concerned about frequent flooding, indoor mold, and asthma. The project documented high rates of asthma and indoor mold in the homes, which garnered the attention of the city council. The second project is an assessment of tap water quality during rain events in another flood-prone neighborhood in which residents report smelly, brown tap water during heavy rainfall. This study is ongoing with residents collecting samples of drinking water and floodwater during rain events that will be analyzed for microbial and chemical contaminants.

Community-engagement in EH research can be successful if built on the understanding that the community has valuable knowledge that can improve the scientific process. Sharing financial resources with the community emphasizes the value of community knowledge and community leadership in addressing local EH concerns. It also helps build trust in the community. This trust is further established when researchers are present in and listening to the community. Community-engaged EH research can serve as a model for scientific investigations that both further the science and directly benefit the local community.

DISCUSSION

Of the four examples given above, the first two had limited funding and a direct focused project which had some immediate success in forging relationships and having some influence on the community and on creating new ideas and change. Their shortcomings however, were in their lack of sustainability and therefore limited impact. Although lessons were learned from these experiences, the communities they served were likely left with incomplete closure and possible frustration, which may have resulted in a measure of distrust towards potential future relationships of this kind.

The second two examples demonstrate that with ample resources and a stable and effective supportive infrastructure much can be achieved. In both, there is clearly stakeholder buy-in and active participation in making the project a success. This process speaks to the mutual satisfaction of the academic institution and the community agencies and organizations. PARTNERS had a singular focus – and the school-based clinics – with the seeding of a model of service that was found not only to become functional, but also documented real benefits for all. The Exposome concepts include a varied set of community-defined projects that organically grow from communities engaged with researchers. Both models are effective and also have demonstrated sustainability.

The challenge posed at the beginning of this paper, that of the town of Fort Valley Georgia, is a different. Because of past false steps and disappointments, the first challenge is to develop a relationship with the people of the town. We must begin to listen to the citizens about how they perceive both the healthy aspects of their community and the health issues facing their children. Our focus is on the environment, particularly indoor air, and the prevalence of asthma as well as the frequency of asthmatic episodes and the severity of the episodes. But that may not be the main concern of the community. Once we can hear their concerns and dreams, we can then work with them and empower them to take charge and ownership of their identified problem while we provide the necessary support, information and technical assistance to make it happen. To increase the probability of attaining the desired goals of all, we aim to work within the frameworks for effective community engagement outlined below. Community partnerships are not built overnight [25, 26]:

- A trusting partnership is developed over months or years.
- A partnership does not depend on a single grant, or even a succession of grants.
- The partnership continues even when there are no grants.
- A partnership means that resources and control are shared.
- The academic institution or government agency must be prepared to share funds with the community.
- The community should be the “senior partner” on issues that affect it.
- Community representatives should primarily be people who live in the community.

Notes on Community Engagement

Involving the community and collaborating with its members are cornerstones of building the public's health. In recent years, community engagement and mobilization have been

essential to programs addressing smoking cessation, obesity, cancer, heart disease, and other health concerns. Recognizing that community involvement is essential to the identification of health concerns and interventions, community engagement is increasingly recognized as a vital component of efforts to expand access to quality care, prevent disease, and achieve health equity for all Americans.

I am convinced that Americans need to live and work in environments where they can practice healthy behaviors and obtain quality medical care. Social, cultural, physical, and economic foundations are important factors in the overall health of the community. We must use our resources to increase availability of healthy foods, ensure that neighborhoods have safe places for physical activity, and provide access to affordable, high-quality medical services. Creating these healthy environments for people of all ages will require their active involvement in grassroots efforts. Private citizens, community leaders, health professionals, and researchers will need to work together to make the changes that will allow such environments to flourish.

Regina M Benjamin, US Surgeon General, 2011. [27]

In practice, community engagement is a blend of science and art. The science comes from sociology, political science, cultural anthropology, organizational development, psychology, social work, and other disciplines, and organizing concepts are drawn from the literature on community participation, community mobilization, constituency building, community psychology, and cultural influences. The art comes from the understanding, skill, and sensitivity used to apply and adapt the science in ways that fit the community of interest and the purposes of specific engagement efforts. We present below a few of the key concepts underpinning successful community health promotion.

Culture

In order to develop a relationship with the community it is critical not only to have an understanding the practicalities and the conditions in the community but also to understand the language and culture of the community. Culture can be seen as a complex integrated system of thought and behavior shared by members of a group — a system whose whole pattern allows us to understand the meanings that people attach to specific facts and observations. Culture shapes identities and fosters notions of community, and it shapes how individuals and groups relate to each other, how meaning is created, and how power is defined. Furthermore, culture shapes ideas about partnership, trust, and negotiation. Therefore, culture shapes the process of community engagement, and effective engagement requires an understanding of culture.

Empowerment

The process of empowerment is a particularly challenging one. Empowerment has been articulated as “a group-based participatory, developmental process through which

marginalized or oppressed individuals and groups gain greater control over their lives and environment, acquire valued resources and basic rights, and achieve important life goals and reduced societal marginalization.” Ideally, empowerment is both a process and an outcome of community engagement and should take place at three levels: the individual, the group, and the community [28].

Social Ecological Model

The social ecological model conceptualizes health broadly and focuses on multiple factors that might affect health. The social ecological model incorporates the understanding and appreciation of the interaction between the individual, the group or community, and the physical, social, and political environments incorporating the social determinants of health (see Figure 2).

Figure 2. The social-ecological model: A framework for prevention.

The Social Ecological Model (SEM) is a theory-based framework for understanding the multifaceted and interactive effects of personal and environmental factors that determine behaviors, and for identifying behavioral and organizational leverage points and intermediaries for health promotion within organizations [29].

CONCLUSION

Building trusting relationships takes time, but it is key not only to providing the most appropriate and useful information, but also to bringing the community into a lasting network of relationships they might draw upon for future needs (and to perhaps help others in similar situations or build regional networks of empowerment). Overall this process serves to improve the health of children who grow up in vulnerable circumstances and who would live more fulfilling and productive lives with good health and prospects for a future, with a good education and good health care. It is our job to help make this a reality.

ABSTRACT

Maternal mortality is a global public health challenge, with 99% of deaths occurring in developing countries. Poor pregnancy outcomes reflect a cycle of vulnerability to risk factors, most of which can be prevented. We propose the creation of an electronic system ('Mommy') that will assist and monitor the health of pregnant women, minimize their exposure to risk factors and break the cycle of maternal mortality. We predict that implementation and widespread use of Mommy may lead to healthier pregnancies and reduce the number of both maternal and neonatal deaths. This project will help to break the cycle and reach the Sustainable Development Goal 2030 of reducing maternal mortality and improving infants' health.

Keywords: maternal health, surveillance, mobile application

INTRODUCTION

Maternal mortality is defined as the death of a woman during pregnancy or in the first year after delivery. The World Health Organization (WHO) estimated that 830 women die every day from preventable causes related to pregnancy and childbirth, with 99% of all

* Corresponding Author's Email: juhcarmona@gmail.com.

maternal deaths occurring in developing countries, and predominantly among young women from low-income populations. The high rate of maternal deaths reflects the social determinants of health (e.g., race, income, education, physical environment, among other characteristics) and highlights the health gap between rich and poor [1, 2].

Pregnancy is a vulnerable period for both mother and fetus, and many factors can increase their risk [3-6]. These factors can be divided into five categories [7]: 1) Preexisting health conditions; 2) Age; 3) Life style; 4) Pregnancy conditions and 5) Environmental risks [8-9].

With advances in technology, it has become useful to apply existing resources to improve health and well-being. To this end, the term mHealth (mobile health) was created. mHealth is a general term for the use of mobile phones and other wireless technology in medical care [2]. The most common application of mHealth is the use of mobile phones and communication devices to inform users about preventive health care services anywhere in the world. Through smartphone technology, mHealth intends to change the face of modern medical assistance, creating mobile systems that collect and analyze data and interact with people.

The risks on the gestational period can be reduced and neonatal outcomes can be improved when the appropriate preventive measures are taken. Smartphone technology can be used as a preventive and efficient method that can be easily harnessed and implemented and it is also practical for women in childbearing age.

Objectives

To develop a computational system to monitor and assist pregnant women to prevent or minimize their exposure to environmental risk factors that can be harmful to themselves and/or their children.

Hypotheses

The technology of smartphones can be harnessed to prevent complications during pregnancy, and decrease maternal and neonatal death rates. This modern tool will allow improved patient monitoring, more personalized care and increase physician and patient satisfaction.

Contextualization

Maternal mortality is one of the major health problems in Brazil and other developing countries [10]. The direct causes of maternal mortality are hemorrhage, sepsis, hypertensive disorders, unsafe abortion, and prolonged and/or obstructed labor [11]. The indirect causes of maternal death are related to poor health before pregnancy, or diseases that women develop during pregnancy [12]. Virtually, all the direct causes are treatable and can be prevented if women receive appropriate prenatal care. Furthermore, some factors (sepsis, unsafe abortion,

hypertensive disorders) are clearly and directly related to the social determinants of health (SDH).

The Pan American Health Organization (PAHO) evaluated the maternal mortality ratio (MMR) in the Americas: the MMR fluctuated from 5.9/100,000 live births in Canada to 690/100,000 live births in Haiti, illustrating the extreme socioeconomic inequality in the region. In Brazil, the MMR has been reduced in the last 18 years from 120/100,000 live births in 1990, 64/100,000 live births in 2005 to 58/100,000 live births in 2008, but the rate did not reach the expected threshold defined by the United Nations [10]. According to the fifth Millennium Development Goal, the annual reduction for MMR in Brazil should have been 5.5%, but it was only 4% [9-10].

Neonatal mortality is frequently used as an indicator of quality of life and well-being of a population [13-15]. Mortality on the first days of life reflects the complex relationship between biological, socioeconomic and welfare factors where socioeconomic and welfare factors are strongly related to the care provided to pregnant women and the newborn [16, 17]. Neonatal mortality rates in developing countries remain alarming: in Bolivia there are 37.49 deaths per 1,000 live births [2], in Africa there are 55 deaths per 1,000 live births, and in Brazil the ratio is 13.82 deaths per 1,000 live births [16]. The major causes of neonatal mortality are related to diseases during pregnancy and childbirth: mainly preterm birth, low birth weight, respiratory and infectious diseases, and congenital malformations [9]. Neonatal mortality is inextricably connected with maternal health conditions [18]. The risk factors of pregnancy can be divided into five categories [7]:

- *Pre-existing health conditions:* These are conditions that are present before women become pregnant, for example diabetes and obesity.
- *Age:* Pregnant teenagers have higher probability of developing high blood pressure, anemia, and are more likely to deliver prematurely. Also, teenagers are less likely to access pre-natal care and do not always understand the risks of pregnancy. Women who have their first child after 35 years of age usually have a normal pregnancy, however they have a higher risk to have a caesarean section, to have complications in childbirth, and their child have higher risk of having genetic conditions, such as Down syndrome.
- *Life style:* Pregnant women who consume alcohol have a higher risk of premature birth, and infants with Fetal Alcohol Syndrome. Women who smoke during pregnancy also put their fetuses at risk of premature birth, genetic abnormality, and sudden death syndrome. Passive smoking or 'second hand smoke' also increases the risk of health problems in both fetus and mother.
- *Pregnancy conditions:* Multiple pregnancies (i.e., twins, triplets, or more) increase the risk of premature birth and frequently require cesarean section. Infants from multiple pregnancies, in general, are smaller and more likely to be premature than singletons. Also, premature infants are more likely to have respiratory distress with associated increase in morbidity and mortality.
- *Environmental risk factors:* Environmental exposures as, for example: air pollution and pesticides may cause premature birth, low birth weight, and congenital malformations. These babies have a higher risk of dying, and those who survive have

higher risk for brain, respiratory and digestive disorders. Environmental exposure is also related to the development of heart diseases and diabetes in adulthood [8-9].

Figure 1. International cycle of environmental health disparities [23].

According to the World Health Organization, maternal deaths significantly reflect social determinants of health, limited access to adequate health care and lack of timely information [1]. Neonatal mortality reflects complex relationship between environment, genes, socioeconomic status, access to health services, and maternal literacy status. Neonatal mortality can thus be prevented by stronger public health policy targeting antenatal and immediate postnatal care [19-22].

Figure 1 shows the cycle of environmental health disparities. This project focuses on to prevent the health risk factors and consequently to break this cycle by offering the pregnant women information, and a facilitated contact with the physician.

RELATED WORK

Many mHealth systems are currently in use, and those focusing on improving maternal and neonatal health have been well received [23]. “Wired mothers” is an mHealth application that combines communication, education on pregnancy, reminders of antenatal care visits, and an emergency medical response system, and has been demonstrated to decrease perinatal mortality rate by 50% [23]. “mMamee” is another mHealth application that does monitor and assess environmental exposures that could potentially affect the health of pregnant women [24]. The platform relies on the combination of user descriptive input and urban sensing

measurements. Their goal is to determine the long-term impact of various exposure factors on maternal and fetal health [24].

A study conducted by Sondaal et al., assessed the effect of mHealth interventions in improving maternal and neonatal care in low- and middle-income countries; the studies, however, have not reviewed used the sensors of the smartphone to obtain environmental data to allow preventive alerts [23].

Mommy is an innovative approach among mHealth applications in that it will use the full capacity of the smartphone by incorporating an environmental sensor to create a more effective prevention tool.

MOMMY ARCHITECTURE

The architecture of the system is shown in Figure 2. The system will have: 1) a mobile application that will be installed on the smartphones of pregnant women; 2) a web system that will be used by the health professional providing prenatal care; 3) a central system that will be responsible to process the information.

The smartphone of the pregnant woman will be the interaction interface of the system: 1) It will collect the environmental data 2) send it to the central system 3) which will process and store the data 4). After processing the data, the system will send alerts and tips to the woman [5 and 6], and include the crucial information into the health professional report [7]. This report can be visualized through the web interface [8].

Pregnant women will register with an email address and password. After that, they will be asked to input some additional information about the pregnancy such as:

- Stage: How many weeks of gestation have passed since last period?
- “Twins information”: How many fetuses is the pregnant carrying, i.e., is it a single fetus or multiple fetus pregnancy?
- Weight: Information about weight gain during pregnancy.
- Symptoms: There will be a list of common pregnancy symptoms that the patient will be prompted to check. There will be also an option to add additional symptoms.
- General well-being: The patient will be prompted to enter information on how she is feeling about sleep quality, mobility, appetite, and other factors during the pregnancy, using a five-star rating bar.

Figure 2. Mommy's architecture.

Shortly after registering, the system will invite her to fill in information about her medical information on conditions, such as personal medical history, family medical history, pregnancy history, and health habits (smoking, alcohol drinking, physical activity) to allow more accurate alerts.

The doctor's report will store the health related information including data such as medications, vaccines, high-risk travel, and physical activity. The doctor's report is crucial for better results, but the pregnant woman will have control over who can access her data. This is especially important for the empowerment of the patient.

The system will provide reliable information throughout pregnancy as the fetus develops. Mommy will also allow the pregnant woman to submit questions and concerns to health professionals. The system will provide instructions to help her recognize signs and symptoms that require further evaluation. A communication channel with the doctor will be available for emergencies.

Other proposed functionalities are the tracking of medication use, and the monitoring of sleep, physical activity, and fluid intake. Tips regarding healthy diet will also be included in the system. The location tracker is fundamental. The women will be alerted if they plan to travel to high risk areas, such as those with high pollution levels or areas with reported cases of Zika.

A prototype of the system was implemented and the Medication Tracker functionality was developed which manages medications that the pregnant woman is taking. Moreover, it reminds her when she needs to take another dose of medication, and it will alert her if the medication that she is taking is not deemed safe during pregnancy.

Although Mommy has been partially developed, it has not yet been tested, and, consequently, has not been released for general use. It was developed to test the system at the Hospital das Clinicas at Ribeirao Preto, Brazil. The technology is currently being elaborated along with the development of new functionalities. This is a work in progress.

DISCUSSION

mHealth interventions have been developed to improve maternal health, antenatal and postnatal clinic attendance, improved vaccination rates, and delivery at staffed facilities [23]. These interventions, however, have shown little impact on maternal and neonatal health outcome [23]. However, as shown by Sondaal et al., none of the methods utilized to develop mHealth applications used the environmental data of the pregnant women to access daily risks. In addition, none of the applications reviewed by the study put together all the functionalities that Mommy proposes.

Mommy intends to access and process the environmental data and send alerts to allow the woman to make changes on her daily habits. There will be also incentive messages seeking to motivate the pregnant women to improve their health habits, making use of multivariate visualization tools to make it easier to understand what the most important aspects are that need to be improved. Furthermore, the system has the potential to be a valuable surveillance tool for doctors in that they can monitor the status of their patients through the electronic reports that will be generated.

The next step of the system development is the medication tracker functionality which will be evaluated and a ‘first version’ will be released to users. Also, new functionalities of Mommy, such as the physical activity tracker will also be developed.

Mommy has the potential to be a functioning health care application that even low- and middle-income populations can access. Technology is becoming more accessible and smartphones are becoming cheaper. There are more than 281 million mobile phones in Brazil, with about three smartphones for each ten people [25]. With a population of 200 million, the number of cellphones exceeds the number of people in the country [26], while the number of doctors is not enough; there are on average only 1.95 doctors per thousand inhabitants with an uneven distribution favoring more urban affluent areas where there are 2-4 doctors per thousand inhabitants while in the poorer areas there are less than 1 per thousand, which is comparable to the poorest countries in Africa [27]. This scenario argues for the potential of Mommy in Brazil particularly for the people living in low resource areas.

By helping to change the mother’s habits that can be harmful to her health and her child’s health and improve her quality of life, we expect to break the cycle of environmental health disparities (see Figure 1) and contribute directly to a better maternal and neonatal health outcome.

ACKNOWLEDGMENTS

We thank Dr. Ligia Marcola, Neonatologist at Santa Casa de Limeira who provided insight and expertise that greatly assisted the research, and the Break the Cycle Team for comments that greatly improved the project.

Chapter 16

DISPARITIES IN ACCESS TO EARLY INTERVENTION SERVICES FOR EXTREMELY PRETERM INFANTS BY FAMILY INCOME

***Marie L. Fefferman^{*}, BA, Bree L. Andrews, MD, MPH

ABSTRACT

This analysis evaluates access to state-provided early intervention (EI) programs among extremely low birth weight (ELBW) infants based on family income. ELBW infants are at high risk for developmental delays in early childhood and at school age. Studies suggest that early intervention programs play an integral role in mediating the health and educational disparities that impact children from low-income households. The Neonatal Intensive Care Unit (NICU) follow-up clinic at Comer Children's Hospital at the University of Chicago has robust data on the developmental status of and early intervention receipt for 131 ELBW infants. Using linear regression analysis to assess this data, we found that for every \$10,000 decrease in median family income, the odds of receiving access to adequate EI services are decreased by 24% ($p < 0.05$). This data demonstrates that infants from low-income families who are at high risk for developmental delays face barriers to accessing EI. Healthcare professionals, EI service coordinators, and families must work together to identify mechanisms for low-income families to access the highest quality of care and support for their children.

Keywords: early intervention, disability, preterm, extremely low birth weight, access, income, intensive care

INTRODUCTION

Infants who are of low birth weight are more likely to experience developmental delays or learning disabilities [1-4]; however, these delays or disabilities can be mitigated through early childhood interventions [5-7]. Children with disabilities or who are at high risk for developmental delays qualify for state-provided early intervention services under Part C of the Individuals with Disabilities Education Act (IDEA). Part C early intervention programs help children ages 0-3 learn basic physical, cognitive, social and emotional skills, while emphasizing the roles that the family and the environment play in a child's development. Despite the fact that these programs have the capacity to greatly enhance a child's development and the parents' ability to work with their child, not everyone who qualifies for EI services is able to receive them. This is especially true for children from low-income families, reinforcing the systemic disparities that these families experience. As such, children from low-income households and who are of low birth weight face a double jeopardy that only intensifies the need to ensure that these children are provided with crucial early childhood supports (see Figure 1).

Part C of IDEA was formulated to implement publicly funded, statewide systems of EI services for young children that may be delivered locally or regionally and mandates that services occur in "settings that are natural or typical for a same-aged infant or toddler without a disability, [which] may include the home or community settings" [8, 9]. Examples of EI services include speech, occupational, developmental, behavioral and physical therapies, family training and counseling, psychological and case management services, comprehensive health and social work services, vision and auditory services, assistive technology devices, and transportation services [10]. In addition to requiring that states provide EI to children with diagnosed disabilities or delays, Part C allows states to opt-in for the provision of EI services for children who are at highest risk for developmental problems [5]. Illinois includes at-risk children in its eligibility criteria, so this Chicago-based analysis studies infants born < 1,000 grams as well as children experiencing brain injury who are at high risk for developmental delays in early childhood and at school age.

Due to their broad scope, EI services benefit not only the child in isolation but also the child's family by fostering familial relationships that will create a less stressful and more supportive home environment. In the National Early Intervention Longitudinal Study conducted by SRI International, 59% of participants reported that their families were much better off after receiving EI services [7]. According to Adams et al. [8] infants who received EI services had improved verbal abilities, receptive language scores, and overall cognitive performance at 8 years of age [8]. Importantly, studies have also shown that EI particularly benefits children from low-income households [5]. Even further, significant economic returns make early intervention an especially attractive policy direction. James Heckman, a Nobel Laureate and University of Chicago economist, has demonstrated that investments in early childhood development, specifically among disadvantaged children, provides the largest rate of return compared to other human capital programs such as schooling later on in life or job

training [6]. Despite these demonstrated benefits, concerns of access arise for children and their families. In a 2008 study, Rosenberg et al. [11] found that at 24 months of age, only 10% of children who exhibited delays received early intervention, with particularly poor rates of access among black children from low-income households [11].

Figure 1. Breaking the cycle of environmental health disparities.

Figure 2. Steps to receive early intervention services.

In order to receive services, families must navigate through a series of steps (see Figure 2). First, the family receives an EI referral from a health, social service, or rehabilitation professional; alternatively, parents, upon noticing a potential delay in their infant, may contact their local EI center. It should be noted that the method by which EI services are distributed varies by state; for example, Illinois services are distributed via EI centers that are spread throughout the state, whereas some states' EI programs are organized through single state offices. Once families are connected with an EI center, the child is screened and evaluated in order to assess whether he or she is eligible for services. After eligibility is confirmed, the caseworker will conduct an initial assessment of both the child and the family in order to identify the specific areas of need. These assessments allow the caseworker to draft an individualized family service plan (IFSP), which describes the services that the child will receive, the child's current developmental status, payment details, steps to transition into and out of EI, when and where the child will receive services, and the anticipated results of the services [12].

The aim of this study is to identify and evaluate the factors that affect access to early intervention services among extremely low birth weight infants. Two factors are of primary interest: 1) family income and 2) the extent of neurological impairment after critical illness in the NICU. This paper also considers barriers that prevent families from receiving the necessary EI services and offers suggestions to overcome these barriers.

Extremely preterm infants were followed from the time they were admitted to the NICU until approximately three years of age, capturing the full eligibility age range for Part C services. Given their extent of prematurity, these infants experience significantly higher rates of learning disabilities and developmental delays than their term counterparts. Msall et al. [2] found that out of 149 children who were extremely premature at birth, 9% of them required intensive special education services, 42% of them required some level of special education services, and 15% of them were at risk for needing additional special education resources as

the educational curriculum became more challenging. Therefore, extremely low birth weight infants constitute a very high-risk population that is in need of support resources and systems of family-centered coordinated care after experiencing life-threatening neonatal illness. By focusing on children who experience the double jeopardy of an extremely preterm birth and poverty during early childhood, this study considers the interplay between the social and biological factors that influence a family’s ability to access developmental healthcare resources.

METHODS

From 2008 to 2014, the University of Chicago Hospitals enrolled 279 extremely low birth weight infants in a clinical trial consisting of two dosing schedules of inhaled nitric oxide for the purpose of evaluating the extent of conferred neuroprotection. Developmental status and provided services were documented for all patients within this “NOVA II” cohort. The patients within this cohort compose this study’s patient population.

Clinical Intuitions Study

The clinical intuitions study is an ongoing study directed by Dr William Meadow at the University of Chicago Hospitals. This study collects data on medical staff members’ longitudinal intuitions on infant mortality and morbidity and the extent of neurodevelopmental impairment in the Neonatal Intensive Care Unit at Comer Children’s Hospital. These infants require mechanical ventilation and have been enrolled in this study with parental consent. Nurses, residents, nurse practitioners, fellows, and attending physicians are asked the questions in Table 1 while the infant is ventilated in the NICU. To analyze these intuitions, the worst intuition on any given day was assigned a numerical score, excluding low-level confidence predictions (see Table 2). In most cases, this method provides an accurate demonstration of each patient’s predicted status; however, for a select few patients, the worst intuition was an outlier.

Table 1. Clinical intuitions study survey questions

Q: Do you think that the patient will live to go home with their family, or die before they are discharged from the hospital?
A: Live/Die
Q: How confident are you about your answer?
A: Low/Medium/High
<i>If staff member predicts that the patient will live to discharge, continue to next question.</i>
Q: Do you think that the patient will experience neurological delays?
A: None/Mild/Moderate/Severe
Q: How confident are you about your answer?
A: Low/Medium/High

Table 2. Clinical intuitions study scoring

• 0 – no impairment predicted
• 1 – mild impairment predicted
• 2 – moderate impairment predicted
• 3 – severe impairment predicted
• 4 – death before discharge predicted once
• 5 – death before discharge predicted by more than one healthcare team member on a given day
• 6 – death before discharge predicted by all healthcare team members on a given day

Adequate	49.2

The NOVA II trial and the clinical intuitions study were conducted in the same NICU at Comer Children's Hospital, and the patients who were enrolled in both studies are the subjects of this analysis. The sample consists of 131 extremely low birth weight (<1000 g) infants (mean gestational age: 25.9 weeks, SD: 1.8 weeks; mean birth weight: 784 grams, SD: 200 grams) (see Tables 3-8).

The Bayley Scales of Infant and Toddler Development is a standard assessment that evaluates a child's developmental status. The Bayley Scales of Infant and Toddler Development scores (see Table 9) were obtained through the NOVA II trial data and are included in order to validate the clinical intuitions scores. To do so, a linear regression evaluating the relationship between the Bayley scores and the clinical intuitions scores was performed, resulting in a significant and positive relationship that aligns the two measures of development (coefficient: 0.53, p-value: 0.05). For this regression, it was important to consider all three of the Bayley measures of development—cognitive, motor and language—and thus each infant was assigned a score that reflected the number of measures out of the three in which the child scored below a score of 85 (one standard deviation below the mean score of 100).

Therefore, although predictions from the clinical intuitions study are collected during the infant's first few months of life, they do have the power to predict neurodevelopmental outcomes for critically ill infants. Additionally, researchers from the University of Chicago have noted the predictive power of these clinical intuitions [13].

Family Income

Family income was estimated based on the family's full address using 2010 U.S. census data. The family's full address as of January 2016 was entered into the FFIEC Geocoding/Mapping System to determine the 2010 median family income for each tract [14].

Access to Early Intervention Services

Physician notes in electronic health records were examined from the time of admission to the most recent physician note entry. These notes provide the primary care physician's assessment of whether or not the child received EI services and the extent of services received. Medical staff members including neonatologists, pediatricians, social workers, and speech pathologists referred all patients and families to early intervention services. Patients received a "0/None" if no EI services were received, "1/Inadequate" if a portion of indicated services were received but a clinician noted that the child or the family's needs were not being met, and "2/Adequate" if all referred services were received without undue complications. In order to run linear regressions, EI access codes were categorized into two groups: 1) adequate receipt and 2) not adequate receipt (none or inadequate).

Data Analysis

Logistic regressions and models were produced using StataSE 13. The model adjusts for sex, race, predicted neurodevelopmental impairment (clinical intuition score), and birth weight. Gestational age was originally included as a control but was later omitted due to collinearity concerns. Gestational age, birth weight, race, and sex were obtained from electronic health records. Studies demonstrate that race and sex are significantly related to receiving EI services, and children with delays are seven times more likely to receive services than children without delays [11].

RESULTS

Out of 128 families, 21.9% had a median family income below 150% of the 2016 federal poverty line for a household of three people [15]. The sample's demographics largely replicate those of the community surrounding the University of Chicago (see Tables 3-7). We hypothesized that family income and the extent of developmental delay would affect EI access with higher incomes and more severe delays being associated with a greater likelihood of receiving adequate EI. We found that for every \$10,000 decrease in median family income, the odds of receiving access to adequate EI services are decreased by 24% ($p = 0.025$). Figure 3 further illustrates the significant discrepancy in access by family income. The probability of receiving adequate EI services is 37% for families with a median income of \$20,000; in contrast, for a family with a median income of \$140,000, the probability of receiving adequate EI rises to 86%. Therefore low-income families with babies who 1) were extremely low birth weight and thus were at high risk for developmental delays; 2) received referrals to early intervention services; and 3) are in fact experiencing developmental delays (see Tables 8-9 for Bayley and clinical intuition scores) are not receiving adequate access to early intervention services. It is also worthwhile to note that even for a median family income of \$80,000, the probability of receiving adequate EI services is still only 65%. Furthermore, approximately half of the children in this sample did not receive adequate EI (see Table 7).

Predicted neurodevelopmental impairment (clinical intuitions scores) did not have a significant effect on access to adequate EI services. Among those who did not receive any EI services, 19% of them were predicted to have greater levels of neurodevelopmental impairment, whereas among those who received inadequate services, 64% were predicted to have greater levels of neurodevelopmental impairment (see Figure 4). The infants' clinical intuitions scores are concentrated around scores of 2, 3 and 4 (moderate impairment, severe impairment, and death before discharge predicted once, respectively). Both the clinical intuitions scores and the Bayley scores demonstrate that these extremely low birth weight infants are experiencing developmental delays.

For male children, the odds of receiving adequate EI services are decreased by 62.8% compared to female children ($p = 0.024$).

DISCUSSION

This paper evaluates access to state-provided early intervention services for extremely low birth weight infants, specifically focusing on the relationship between family income and access to early intervention services. At the time of discharge from the NICU, there are

numerous social and public factors that impact how NICU ‘graduates’ access community support services. Early intervention programs take advantage of the crucial window of early childhood brain development, and recent studies suggest that interventions during the first few years of life play an integral role in mediating the health and educational disparities that low-income children experience in settings of high biomedical or social risk. Trajectories of developmental delays can widen during middle childhood and adolescence, setting the stage for lifelong physical, behavioral, and social health challenges. The consequences of these missed opportunities for secondary developmental prevention significantly impact the child, family, and community. Given our financial and societal constraints, developmental healthcare resources must comprehensively target those who are most vulnerable; specifically, our enabling efforts must prioritize children experiencing social disadvantage and who are at the highest biomedical risk for developmental delays or disabilities. The Bayley assessments provide valuable developmental information, but caretakers gain this information at a time when it is much harder to mobilize services. Bayley assessments are typically conducted between 18 and 24 months of age, leaving approximately one year for families to navigate the EI system (see Figure 2) and to start using EI services before their children age out of the system at 3 years of age. With the data from the clinical intuitions study, physicians and families may have an understanding of the delays that a child will have going into early intervention. Additionally, infants who are especially at risk may be identified well before they leave the NICU.

Biological Factors and Developmental Healthcare Resources: Prematurity

With 1 in every 10 US births being preterm, it is valuable to consider how we might use early interventions to manage the potential consequences of an early arrival [17]. Although preterm infants have an increased mortality rate, most neonates survive but experience a range of health and developmental adverse effects. Preterm infants face an increased chance of developmental delays, breathing problems, vision problems, and hearing impairments [17]. These issues only intensify as birth weight decreases [3]. The prevalence of preterm birth combined with the increased risk of physical and mental complications compels us to offer services, such as early intervention, that help families and children cope with the effects associated with prematurity. For the most part, experts have not discovered specific physiological mechanisms through which preterm labor occurs, so researchers have put their energy toward identifying risk factors. Various factors such as having a low-income, a lack of education, experiencing unemployment, or having limited support networks may put mothers at risk for preterm labor [1]. Race is also a significant risk factor, as almost 17% of black babies are preterm compared to less than 10% of white babies [1].

Social Factors and Developmental Healthcare Resources: Family Income

Social factors strongly influence a child’s developmental progress and existing social structures can make it nearly impossible for families to sufficiently support their child’s developmental growth. These challenges may lead to decreased kindergarten readiness rates,

suboptimal educational achievement on standardized assessments as part of the No Child Left Behind Act and decreased high school graduation rates and attendance at community college. Furthermore, there are often decreased life course outcomes in employment, income, and social independence. A study from the Center on Children and Families at Brookings Institution examines the relationship between family income level and the percentage of children who were school-ready by the age of five. Only 48% of children from poor families were kindergarten-ready, whereas 75% of children from moderate or high-income families were kindergarten-ready [18]. This 27-percentage point difference demonstrates that low-income families face more challenges regarding their child's developmental trajectory. Importantly, the age at which a child experiences poverty matters: poverty experienced during the first five years of life strongly influences the number of school years a child may complete. Poverty experienced after age five has a significantly smaller impact on school completion [19]. For low-income families with a child below the age of five, a \$10,000 increase in mean family income allowed for nearly one additional school year to be completed [19]. This crucial early childhood window demands that developmental health and educational resources are provided to high-risk children as early as possible.

Intensifying these considerations, poor neighborhoods may be less socially organized and are often complicated by issues such as high crime and school dropout rates as well as low employment rates [20]. All of these factors influence development, and this reality is only worsened by the lack of resources in poor neighborhoods such as limited access to day care programs, museums, libraries, playgrounds, healthcare facilities, and after-school programs [21]. These multidimensional and complex issues reveal a susceptible population that needs appropriate early interventions in order to provide the best support and care possible. With this in mind, early intervention becomes a critical source of support that can prepare children with delays or disabilities for success, especially among low-income populations. Although all children should receive the best education and healthcare possible, low-income families experience compounding risk factors that make them especially vulnerable to the cycle of disadvantage (see Figure 1) since poverty intensifies and reinforces the problems that are associated with healthcare and educational disparities.

Gender and Developmental Healthcare Resources

Male preterm infants experience worse developmental outcomes than female preterm infants, and male sex is a risk factor for poor neonatal, neurological, and respiratory outcomes [16]. Janet Peacock et al. [16] reported that some level of disability was present in 53% of preterm males compared to 39% of preterm females at 24 months of age. Considering this, it is particularly concerning that male children have more difficulty accessing adequate EI services (see Figure 5). Hintz et al. [23] asserts that worse neurodevelopmental outcomes in males are likely due to unmeasured biological variables. However, the discrepancy in access to EI for male children may call for a reanalysis: perhaps the lack of developmental support for male children plays a role in the developmental disadvantage that male infants experience, which adversely impacts this population throughout adolescence and adulthood.

Barriers to Early Intervention Services

Considering the numerous steps that families must go through to receive EI services (see Figure 2), the process can become quite complicated, often resulting in a failure to provide or receive services. Jimenez et al. [22] identified barriers to early intervention services by interviewing EI employees, families with EI referrals but who were not evaluated, and families with EI referrals but who were evaluated. Five main themes emerged: 1) parents described communication problems with their pediatrician; 2) many parents believed that they were the best judge of their child’s development, and thus they should be the ones to decide whether or not their child received services; 3) some parents wanted to wait and see how the child’s development progressed without services; 4) practical obstacles caused ambivalent parents to stop the EI process; and 5) EI employees expressed that they believe families avoid evaluation since they mistake EI employees for child protective services [22]. These perceived and real barriers, although substantial, may largely be resolved through improved communication between all of the involved actors (families, healthcare providers, and EI employees). It also seems that physicians may play a profound role in improving access since many families did not agree with their primary care provider’s decision to refer their child to EI. Among families who were not evaluated by an EI caseworker, 63.6% were in denial or disagreement about their child’s EI referral, whereas out of those who were evaluated, 18.2% were in denial or disagreement [22]. This suggests that working with families to illustrate the benefits of EI and explaining the reasons for referral will help children to receive the necessary services.

Figure 5. Access to early intervention services by gender.

Practices to Improve EI Service Delivery

All of the babies in this sample spent a number of months in the NICU before they could be discharged from the hospital. This provides an opportunity to ensure that families fully

understand the benefits of EI services and to guide them through the EI process. During their time in the NICU, families have easy access to physicians, nurses, and social workers who can and should help families connect to early intervention centers. In an attempt to guarantee that the highest-risk infants have access to services as soon as possible, the EI process should begin before the infant is discharged from the NICU.

According to Dr Bree Andrews, a neonatologist and the director of the NICU follow-up clinic at Comer Children's Hospital, EI caseworker reluctance to visit specific neighborhoods can substantially impact a family's ability to receive services [24]. Understandably, caseworkers may refuse specific cases out of concern for their own safety or comfort level. Although this is a reasonable feature of the program's organization, it means that families who live in certain neighborhoods have fewer caseworkers available to them, posing a serious threat to EI access. To moderate this issue, EI centers may co-localize services—a vast majority of infants who need EI require more than one type of service (i.e., both speech and physical therapy). These services may be packaged and delivered together, at the same time, in the same place. This could help with the issue of caseworker safety, but it would also relieve some of the burden that multiple EI appointments often place on busy families.

National Early Intervention Standards

Because early intervention systems are not standardized on the national level, EI organization and distribution varies by state. This federally granted freedom has led to significant differences in state eligibility criteria. For example, this paper examines at-risk infants; however, most states do not offer services for children who are at-risk, instead, these states only provide services to those who have diagnosed delays or disabilities [5]. This analysis shows that many high risk children require EI, and it seems most likely that these children would be overlooked in a state with less generous eligibility requirements than Illinois's. With a standard set of eligibility requirements that fully acknowledge the impact that EI services can have, more children may receive the appropriate developmental support.

Effectively Allocate Our Limited Resources

Early intervention funding increased from \$81 million in 2002 to \$146 million in 2009; however, from 2009 to 2013, funding has remained relatively stable [25]. Correspondingly, the number of Illinois children served increased from 11,100 children in 2002 to 19,100 in 2009 [25]. From 2009 on, the number of children served by EI has remained constant, mirroring the stagnant post-2009 funding levels [25]. EI funding has failed to account for both inflation and need, leading to an increase in the number of children who need EI but who are not receiving it. The Illinois state budget crisis puts EI programs in constant jeopardy, as EI centers are commonly unable to pay their employees for extended periods of time.

With our current resource limitations, there must be mechanisms in place to ensure that the neediest families are receiving services. This begins by ensuring that families are connected to an EI center before they leave the NICU, but it must extend further toward a cultural shift and a broad acknowledgement of the barriers to access for low-income families.

This data urges us to allocate more of our limited resources to families and infants who are underserved and thus are combatting a multiplicity of health and educational disparities. This engagement and this advocacy process will lead to improved developmental and educational outcomes.

Study Limitations

There are some limitations in generalizing this data since it was conducted in only one hospital system, Comer Children's Hospital at the University of Chicago, and healthcare practices vary by hospital and EI center. In addition, the sample is largely African American (68.5%) and though it reflects much of the concentrated minority status in Chicago, it may not be nationally representative across other urban centers.

CONCLUSION

Through linear regression analysis, we found that for every \$10,000 decrease in median family income, the odds of receiving access to adequate EI services are decreased by 24%, suggesting that low-income families face barriers to services that reach beyond physiological need alone. Male infants also experience discrepancies in access—their odds of receiving adequate EI services are decreased by 62.8% relative to female infants. Predicted neurodevelopmental impairment did not have a significant effect on EI access; however, these clinical predictions may account for the social factors that shape a child's life after they are discharged from the hospital in addition to giving healthcare professionals an early signal about the delays that the child may experience.

This disparity in access reflects a need to have more proactive engagement and support for vulnerable children and families. To try to do this, there must be improved family-centered engagement practices including better coordination and involvement of EI professionals, NICU discharge planners, and pediatricians. Poverty and prematurity feed into and nourish a cycle of environmental health disparities. This cycle travels from poverty to limited resources to premature birth, forcing the next generation of parents and their children into a disadvantaged reality. Figure 1 illustrates this cycle of disparity and illuminates the compounding factors that affect a family's ability to access services. Despite these families' need for support, this paper demonstrates that low-income families are not receiving the necessary and comprehensive developmental healthcare services to which they are entitled.

With the demonstrated discrepancy in access, EI and healthcare professionals, policymakers and families must work in tandem to acknowledge this problem, identify barriers to receiving services, and discover mechanisms to overcome these barriers. By considering a child's developmental needs as early as possible, physicians can proactively help families work with their children to optimize neurodevelopmental outcomes. This consideration must begin while the critically ill child is in the hospital and continue after hospital discharge when low-income families with infants who are extremely high risk need the highest level of family-centered support and care coordination.

ACKNOWLEDGMENTS

We would like to express our sincere gratitude to Dr William Meadow, Lea Redd, Sarah Kennedy, Ren Belcher, and Kristen Wroblewski for extensive research support and collaboration. Finally, we are incredibly grateful for the outstanding “Break the cycle” (BTC) program and the BTC committee members who have made this research possible.

ABSTRACT

The southern region of the United States (US) is home to approximately 20% of the US total pediatric population. Previous research has shown that children in the South experience higher poverty and poorer health outcomes, including higher rates of infant mortality, asthma, and obesity. Access to health care and utilization of preventive medical services are both essential determinants for the well-being of children and youth in the United States. Additionally, the local neighborhood environment has also been shown to be associated with child health and access to health care. Poverty, southern residence, and adverse community characteristics may serve as compounding risk factors for children's access to health care. In order to explore this issue, we analyzed data from the 2011-12 National Survey for Child Health. The primary measures of access to care include having a medical home, preventive medical visit a preventive dental visit. The multivariate logistic regression models included covariates of individual sociodemographic and health characteristics. Poverty, southern residence, unsupportive neighborhoods, measures of built environment, and community marked by decay were independently associated with worse access to health care, after adjusting for all other covariates. Children from low-income households who also live in southern communities

* Corresponding Author's Email: kuangx@etsu.edu.

with disadvantaged characteristics experience multiple factors undermining their access to health care. In order to help break the cycle of disadvantage, an ecological model should be used to guide future interventions for improving access to comprehensive health care services for all children.

Keywords: health care access, medical home, preventive care, health care utilization, poverty, geography, neighborhood environment

INTRODUCTION

Access to health care and utilization of preventive medical services are both essential determinants for the well-being of children and youth in the United States (US). Improving access to quality health care services and promoting timely and appropriate use of preventive services can allow children and youth to achieve the best health outcomes and achieve their full potential [1]. In the past two decades, public health insurance programs, including the enactment of the State Children's Health Insurance Program (SCHIP) initiative and the expansion of the Medicaid program, have expanded insurance coverage for the pediatric populations in the US [2]. Despite these efforts, inequities and disparities in health care access have persisted as a major problem for many American children, especially those from vulnerable and underserved communities.

While a wide range of ecological factors can influence children's access to health care, poverty is often considered one of the most prominent risk factors. The associations between childhood poverty, poor health status, and decreased access to medical care are well documented in the literature [3-6]. In general, children in families living below the poverty threshold are less likely to obtain appropriate health insurance coverage and have a usual source of health care [6]. These children are also more likely to report unmet medical needs and experience more frequent delays of care [7].

Another important factor potentially affecting health care access is geography. The influence of geographic variation in health care access, which is less frequently examined in population health research, is often overshadowed by racial and ethnic disparities [8]. Nevertheless, some researchers argue that regional differences may contribute to a significant portion of the overall health disparities in the US [9, 10]. Home to approximately 20% of the US pediatric population, the South is a distinct geographic region in the United States. The unique identity of the South is brought by its history of racial segregation and discrimination, religious values and traditions, and social conservatism. More importantly, the region has experienced persistent disparities in both poverty and health care for children. Compared to other regions, the South has consistently had the highest child poverty rate in the country [11]. National data provide evidence of regional health disparities for children in the South, including higher rates of infant mortality, childhood asthma, and obesity [12-15]. Additionally, a previous study indicated that living in this region is a strong predictor of poor child health outcomes [10].

In addition to the macro level of regional geographic variations, the local community and neighborhood characteristics are considered micro level of geography which are also important socioecological determinants of children's physical health and their access to care. Researchers have found that the local built environment, such as parks and recreational

facilities, is associated with both increased child physical activity and lower rates of obesity [14, 16, 17]. Another dimension of neighborhood is the social connectedness as measured by human capital and social cohesion. Studies have demonstrated significant associations between parental perceptions of the cohesion and safety of their neighborhood and their children's access to a medical home [18].

While current research has identified disparities in child health outcomes related to poverty, geographic region, and neighborhood characteristics independently, few studies have investigated the combined impact of these risk factors. Furthermore, to our knowledge, none have studied poverty and geography in relationship to children's access to care in the context of preventive care utilization and the presence of a medical home. Using an ecological framework called "Break the cycle" [25], this study examined the role of poverty and geography (as measured by Southern U.S residence and local community characteristic of social cohesion and the built environment) while adjusting for health insurance and other socio-demographic and health status characteristics. The findings of this study will help advance knowledge and understanding of the ecological characteristics and barriers of access to care for the pediatric population in the South. The results of the analyses will help raise awareness and support the development of region-based health interventions that aimed at breaking the cycle of environmental and other child health disparities in the South.

METHODS

Our study is built upon the ecological model of "Break the cycle" created by colleagues at Southeast Pediatric Environmental Health Specialty Unit in Atlanta, GA (see Figure 1). The model takes a systematic approach to understanding the interconnectedness between social, economic, and environmental risk factors as related to health care disparities among children. It posits that the personal socioeconomic circumstances, compounded by environmental disadvantages, can lead to limited access to social and health care services for children, and as a result, increasing their chances of having developmental disabilities and other chronic medical conditions. Children who fall short of their full potentials and well-beings may ultimately encounter further issues and disadvantages as they transition into adulthood, as the cycle continues. This ecological framework offers a creative guidance to address health care challenges by looking broadly at various factors on both individual and community level, and by doing so to break the cycle of disadvantages [25].

Data Source

This study used cross-sectional data from the 2011-2012 National Survey of Children's Health (NSCH). The NSCH is a national population-based telephone survey designed and conducted by the National Center for Health Statistics at the Centers for Disease Control. The survey generates a broad range of information about children's health and well-being to help guide healthcare providers, researchers, advocates, and policymakers. Using a random-digit-dial sample of both landline telephone and cell phone numbers, the survey identified and sampled households with one or more children under 18 years old. Within each household, a

parent or guardian was interviewed about a child randomly selected in the family. A total of 95,677 surveys were collected nationally for the 2011-2012 NSCH with each state having at least 1,800 completed surveys. The survey results were adjusted and weighted to represent the demographic composition of non-institutionalized children 0-17 nationally [24].

Figure 1. Breaking the cycle at two locations.

Measurements of Health Care Access

Access to care was measured by three dichotomous variables: having a preventive medical care visit in the past 12 months, having a preventive dental care visit in the past 12 months, and receiving care in a medical home. The medical home measure used in NSCH is consistent with the definition developed by the American Academy of Pediatrics (AAP) and includes five sub-components: having a usual source of care, having a personal physician or nurse, receiving all needed referrals for specialty care, receiving needed help coordinating care between multiple providers, and receiving care that is family-centered and culturally sensitive. Respondents were required to meet all five sub-components to qualify as attaining a medical home.

Key Predictors

The main predictor variables were poverty, southern residence, and community characteristics. Poverty is defined as below 100% of the Federal Poverty Level. The household poverty level was imputed from reported family income and size by the NSCH with standards based on Department of Health and Human Services (DHHS) guidelines. The operational definition of the South is from the study by Goldhagen and his colleagues in 2005, where they found significant disparities in children’s health outcomes in nine southern states as compared to other regions of the United States [10]. The Goldhagen’s definition of the South includes these following states: North Carolina, South Carolina, Georgia, Florida,

Alabama, Mississippi, Louisiana, Arkansas, and Tennessee [10]. Children who live in one of these nine states are identified as living in the South while those living outside of these states are considered “Non-South.”

The NSCH includes several questions to assess community characteristics based on the parents and guardians’ perceptions of their children’s neighborhood environment. Our study included the following factors: supportive neighborhood, positive built environment, and community marked by decay. These community environment measurements in the NSCH survey were originally developed and used in other social surveys and were derived from validated measures [18].

Supportive neighborhood also refers to social cohesion or social capital in various contexts. This variable was measured by responses to four statements: 1) People in my neighborhood help each other out; 2) We watch out for each other's children in this neighborhood; 3) There are people I can count on in this neighborhood; 4) If my child were outside playing and got hurt or scared, there are adults nearby who I trust to help my child. The parent or guardian of the child was asked about the level of their agreement to each statement, ranging from strongly agree to strongly disagree. Item responses were then imputed in a numeric scale between zero to four and the average is calculated for eligible cases (those who with valid responses to at least three items). The cases with an average score equal to or above the population mean (2.25) qualify as living in a supportive neighborhood.

Positive built environment was characterized by the positive aspects of the physical environment in the neighborhood. Respondents were asked four questions about the presence of neighborhood amenities, including sidewalk, parks/playground, recreational center and library. For this study, only cases with affirmative responses to all four questions met the requirement of having a positive built environment.

Community marked by decay refers to the negative aspects of the physical environment in the neighborhood. The variable was derived from three survey questions on the presence of detracting elements within the community, including litter or garbage, dilapidated housing, or vandalism. Respondents with affirmative response to just one or more of the three questions were considered living in a community marked by decay.

Covariates

Covariates included age, gender, race / ethnicity, insurance status and type, types of family structure (such as two-parents or single-parent), primary language, highest education level of the parent / guardian, the overall health status of the child, and the presence of special health care needs which was identified through the validated Children with Special Health Care Needs (CSHCN) screener tool used in numerous national surveys.

Statistical Analysis

For the entire sample, diagnostic analyses (collinearity, linearity, independent variance) were conducted to assure that the data met all required test assumptions. A descriptive bivariate analysis was conducted for all variables in the model. For all three outcome

variables, weighted percentages were tabulated for each of the main predictors and covariates. Unadjusted chi-square tests were then used to ascertain statistical associations between the independent variables and dependent variables. The independent effects of the main predictors on the outcome variables were evaluated using multivariate logistic regression analyses while controlling for all other confounders. Covariates that were found statistically insignificant were removed from the subsequent analyses. There were less than 15% missing percentage for all given analyses. All statistical tests were conducted using SPSS software (version 23.0). A p-value of less than 0.05 was considered the indication of statistical significant.

RESULTS

Table 1 presents the overall distribution of sociodemographic characteristics and health care access among all children aged 0-17. There were 95,677 cases in the 2011-2012 NSCH, which represents approximately 73 million children in the U.S. Within the weighted study population, 20.4% of children lived in the South. 22.4% of the population are children living below the poverty threshold. In addition, 17.4% of American children reported they lived in an unsupportive neighborhood, 44% lacked positive built environment, and 28.1% lived in community marked by decay. Nationally, 44.1% of the total population of children lack access to a medical home, while 15.5% and 21.4% respectively did not have a preventive medical care visit and dental care visit in the previous year.

Chi-Square Analysis

Table 2 lists the proportion of children with access to a medical home, preventive medical visit and dental visit in the past 12 months according to demographic, socioeconomic, health status, and health insurance. Statistical differences among the percent of preventive care visits and medical home attainment rates are apparent across our main predictors. Prevalence of medical homes was much lower among children below the federal poverty threshold than those above (36.4% vs 59.5%). Children in poverty also reported lower rates for preventive medical visit (78.5% vs 86.1%) and dental visit (68% vs 79.8%). 53.4% of children from the South had access to a medical home, which was slightly less than children in other parts of the US (54.7%). In comparison, children with southern residence also had lower likelihood of attaining either preventive medical visit (82.1% vs 85%) or dental visit (74.4% vs 77.9%).

In addition, all three community indicators are statistically associated with children's health care access. Nearly 38.8% of children who lacked a supportive neighborhood reported having a medical home compared to 58.3% of those living in supportive neighborhood. Children without a supportive neighborhood also had lower rates for preventive dental visit (70.3% vs 78.8%). Similar observations were found in the measure of positive built environment. Compared to children who have positive built environment, those lacking positive built environment reported worse access to medical home (51.4% vs 57.7%), preventive medical visit (82.2% vs 86.6%) and dental visit (75.4% vs 79.4%). Additionally,

only 46.9% of children from a community marked by decay received care from a medical home compared to their counterparts (57.8%). These children were also slightly less likely to have obtained a preventive medical visit (83.8% vs 84.8%) and dental visit (73.6% vs 78.7%) in the past year.

Table 1. Characteristics of the study population of children aged 0–17 years in United States (95,677), National Survey of Children’s Health, 2011–2012

*Non-Hispanic children reporting only one race category of Asian, American Indian, Alaska Native, Native Hawaiian, or Pacific Islander, or who are more than one race (multi-racial) are grouped as "Multi-racial/Other, non-Hispanic" because of small sample sizes in many states. [†]Households identified as having two mothers of the same type (biological, step, foster, or adoptive) were classified as "other family type."

Results of the unadjusted chi-square analysis showed the children of minority race or ethnicity (versus white) have lower access across all three measures. Children from families whose primary language was not English were dramatically less likely to have a medical home than children with families where English was primarily spoken (26.5% vs 59.3%); in addition, their likelihood of having a preventive medical visit within the past year was also lower (77.2% vs 85.7%). Only 27.8% of uninsured children had access to a medical home compared to those with public (43.9%) and private (64.0%) insurance. These large discrepancies related to insurance type were also present for preventive dental visits (uninsured 47.7% vs public 73.5% vs private 82.5%). More than 62% of children of parents with more than high school education received care in a medical home, compared to less than 39% of children of parents with below high school education. Interestingly, although children

with the special health care needs were reported to have higher rates of preventive medical and dental visits, they were less likely to have a medical home when compared to children without special health care needs (46.8% vs 56.3%).

Multivariate Logistic Regression Analysis

Table 3 presents adjusted odds ratios, 95% confidence intervals and p-values from the multivariate analysis of the factors that influence children's health care access. After the adjustment for covariates, poverty remained as a significant factor for health care access. Compared to those who are not in poverty, children from families below poverty threshold were less likely to have a preventive dental visit in the past year (OR = 0.74, $p < 0.001$), less likely to have a preventive medical visit in the past year (OR = 0.79, $p < 0.001$, and less likely to have access to a medical home (OR = 0.82, $p < 0.001$). Southern residence also had an independent effect on health care access. Compared to children living outside of the southern region, children from the South were less likely to have a preventive medical visit (OR = 0.86, $p < 0.001$) and a preventive dental visit (OR = 0.94, $p < 0.05$). However, in contrast to the bivariate results, children from southern states had slightly higher odds of having a medical home than those not living in the South (OR = 1.08, $p < 0.001$).

In addition, the multivariate analysis also showed that measures for community characteristics were each directly associated with health care access. Children living in neighborhoods rated as not supportive had decreased odds of access to a medical home (OR = 0.59, $p < 0.001$) and preventive dental visit (OR = 0.78, $p < 0.001$); but no significant relationship was found with access to preventive medical visit. Children living in communities that lacked a positive built environment were less likely to have a medical home (OR = 0.86, $p < 0.001$), preventive medical visit (OR = 0.81, $p < 0.001$) and dental visit (OR = 0.86, $p < 0.001$) than children living in communities with all four aspects of the built environment. Lastly, compared to children living in communities without decay elements, children living in neighborhoods marked by decay showed lower odds for the attainment of medical home (OR = 0.879 $p < 0.001$) and the receipt of a preventive medical visit (OR = 0.93, $p < 0.001$) and a preventative dental visit (OR = 0.86, $p < 0.001$).

In addition to key predictor variables, other covariates also had individual effects on health care access. Being uninsured, having only public insurance, and low parental educational attainment were all significant risk factors for not obtaining recommended preventive medical visit and dental visit as well as not having a medical home. Race and ethnicity are independently associated with health care access. Adjusting for other factors, children from minority racial and ethnic groups still showed lower odds for the attainment of a medical home, but higher odds of having a preventive medical visit in the past year compared to White children. Statistical significance were found in the direct association between primary language and access to medical home or preventive medical visit but not with dental visit. The presence of special health care needs was associated with higher likelihood of getting timely preventive medical visit and dental visit, but was associated with a lower odds of access to a medical home.

DISCUSSION

Utilizing data from a nationally representative sample of families and children, we found that children were less likely to have access to timely preventive health care if they are poor, living in the South, and come from neighborhoods characterized as unsupportive, lacking a

positive built environment or marked with decay. These associations remained independently significant even after controlling for demographic, socioeconomic, health status and health insurance characteristics of the children and their families. Therefore, our study provides additional evidence that poverty and both macro and micro geographic characteristics are important factors in supporting equitable access to care for all children.

Our study focused on the potential health care access disparities among children living in the southern region as compared to the rest of the US. The results of the multivariate logistic regression analysis demonstrate that children from the South lag behind their peers on both timely preventive medical care visits and dental visits compared to their counterparts outside the south even after adjusting for all other socioeconomic and health factors. However, the southern region is associated with slightly greater adjusted odds for access to a medical home than non-south. The concept of medical home is relatively more complex, subjective and relative to parents' expectations for care. Therefore, the higher rates of medical home attainment in the South could result from potential bias towards overestimation within the rural and poor population that perhaps has lower health literacy.

Why do children in the South have worse access to preventive health and dental visits? Past research has indicated that the receipt of preventive health care services is strongly associated with insurance status [19]. While our analysis controlled for type of insurance (private, Medicaid and uninsured), we did not measure other insurance-related barriers such as the relative payment rates. Southern states have the highest child uninsured rate in the country [15]. Southern states' Medicaid programs (with some exceptions) have some of the lowest reimbursement rates in the country. This is reflected in the fact that all southern states in our study ranked below the US average for Medicaid spending for pediatric enrollees [20]. The combination of low overall insurance rates and lower reimbursement rates are associated with worse access to health providers that decline to accept Medicaid patients or limit the number of Medicaid patients in their practice.

The significant association between child poverty and lack of health care access has been documented in multiple studies [3-6]. Consistent with previous research, our study found that children living below the poverty threshold had worse access to primary healthcare services. Poor children were less likely than their non-poor counterparts to report having a medical home and were less likely to have preventive medical and dental visits in the previous year. While poverty has been a common topic in the discussion of healthcare disparities, it nevertheless is an important driver for other social determinants of health, and as such, it acts as a centerpiece for our research. As stated previously, the child poverty rate has been disproportionately higher in southern states than other parts of the US [11].

Despite a growing interest in the relationship between social environment and health, there are few studies that measure the impact of neighborhood characteristics on health and health care of children. Some studies assess neighborhood environment using individual-level variables, such as personal income and employment status, which may not be sensitive to structural, social and environmental impact of neighborhoods on service utilization [21]. Additionally, we found very few pediatric articles focused on the interplay between community environment and health care access [18, 22], as a majority of research were focused on the adult population. Our study assesses the association between neighborhood characteristics, as rated by the parents, including social supportiveness, built environment, and decay elements in the neighborhood, with children's health care access, which in turn can impact children's health outcomes. We found that the lack of supportive neighborhood and positive built environment, along with the presence of community decay is associated with worse access to medical home and lack of adherence to preventive visits in addition to southern residence and poverty.

What are the mechanisms or pathways that lead to decreased service utilization for children in these neighborhoods? Parents in less supportive neighborhoods may face

increased obstacles to access health care for a number of reasons. Medicaid transportation only allows the parent and the patient in the transport. Parents in unsupportive neighborhoods may lack neighbors who can watch their other children when they need to go to a medical appointment. The distance to health facilities from impoverished neighborhoods is, on average, greater than from more wealthy neighborhoods. In addition, public transportation may be lacking to allow easy and timely access for parents from these neighborhoods. Lack of a built environment, such as sidewalks, may make it very difficult for parents of young children to walk to public transportation. Lastly, communities marked by decay have increased rates of violence, limiting the ability of families with children to leave their homes, especially at night. Our findings underscore the need to foster collaborative relationships among health care providers, families, and community leaders to identify innovated local solutions to improve health care access for children from neighborhoods with disadvantaged characteristics.

The model of “Break the cycle” in our study signifies a new approach of examining the complex interactions of the impact of socioeconomic (poverty), geographic (southern residence) and ecological (community characteristics) factors on children’s health care access. At-risk children may often experience multiple disadvantaged conditions simultaneously, which can lead to serious implications for the health care access. In our study, we found that both micro and macro geography were independently associated with access to care, compounding the effect of poverty. Therefore, poor children in the South who live in neighborhoods which are less supportive, marked by decay and lack dimensions of the built environment can be subject to multiple risk factors that are cumulative and greatly reduce their access to appropriate health care. In previous research it was found that children experiencing multiple risk factors reported 68% lower odds of having a medical home than those with only one risk factor [5]. Combined risk profiles can lead to larger shortfalls in having appropriate access to quality health care for children. These observations suggest that in addition to acknowledging the single, unbiased effect of each risk factor in research, it is equally important to account for the collective influence of multiple characteristics for healthcare access disparities.

There were several limitations in our study. First, we were not able to determine causal inferences from our data due to the cross-sectional nature of the NSCH. In addition, all questions measured in the NSCH were based on parental reports, such as the measurements for medical home, children’s health conditions, and perceptions of social cohesion and community characteristics. The answers provided by parents in the survey are limited by their knowledge and recollection. To minimize such self-report bias and recall bias, future research may consider triangulating parents’ responses with youth and healthcare providers’ responses or other ecologic studies of access to care. Finally, the design of NSCH may have been subject to selection bias as some groups of children are underrepresented or not represented in the survey, including children living in homeless shelters, those in institutional settings, and those without either landline telephones or cell phones.

Despite these limitations, this study has depicted a detailed and comprehensive examination of the persisting disparities in children’s health care access. This research contributes to the existing body of literature on the impact of poverty, southern region, and adverse neighborhood environment for children’s access to quality medical home and utilization of preventive care services. Our findings also demonstrate the need for applying an ecologic framework, such as the Break the Cycle, to understand the interrelationship and

cumulated effects among regional, community, and personal-level characteristics for access to primary care. Utilizing an ecologic framework may help inform policy changes to support greater access to primary health care delivery and encourage the development of ecologic and population-based interventions that aim in breaking the cycle of disparities for children.

ACKNOWLEDGMENTS

This work was supported as part of the “Break the cycle,” a collaborative interdisciplinary research and training program and annual conference at Emory University funded by the cooperative agreement award number 1U61TS000118-05 from the Agency for Toxic Substances and Disease Registry (ATSDR). We thank our colleagues from Southeast Pediatric Environmental Health Specialty Unit and Innovative Solutions for Disadvantage and Disability Sustainability Initiatives at Emory University who provided valuable feedback that greatly assisted the research.

Chapter 18

**GRANDPARENTS RAISING GRANDCHILDREN
WITH DISABILITIES: ASSESSING HEALTH STATUS,
HOME ENVIRONMENT AND IMPACT OF A FAMILY
SUPPORT CASE MANAGEMENT MODEL**

***Kelly Brown*, BS, Victoria Churchill, MPH,
Elham Laghaie, MS, Fatima Ali, MPH, Shaaz Fareed, BS
and Lilly Immergluck, MD, MS, FAAP***

ABSTRACT

There are 4.2 million households in the United States where grandchildren live with their grandparents. Grandparents who raise grandchildren are at risk for financial strain, poor health outcomes, and poor housing conditions; this is compounded when the grandchildren have developmental disabilities or other chronic medical conditions. We partnered with Project GRANDD (Grandparents Raising And Nurturing Dependents with Disabilities), a program that provides support to grandparents who are the primary caregivers for their grandchildren with disabilities, to determine if family-centered case management, (phone calls, nurse visits, home visits, monthly group meetings, and referrals) had an impact on the grandparents' perception of their own health and their own home environment. We evaluated the impact of the program retrospectively, by reviewing case management documents and prospectively, by administering surveys to grandparents who were enrolled in Project GRANDD. From the 46 grandparents who participated in our study, we determine that Project GRANDD services resulted in overall perceived improved health and home environmental conditions. Specifically, 44 percent of enrolled grandparents reported a health improvement since joining Project GRANDD and 39 percent of grandparents reported an improvement on the condition of their home through the services provided by the program. The potential benefit of this particular family-centered case management model on health and home environment requires

* Corresponding Author's Email: PEDSresearch@msm.edu.

further exploration and study, but our preliminary study suggests that such a model has a positive impact on the health and wellness for these families.

Keywords: multigenerational, grandparents, grandchildren, disabilities, caregivers, health, environment, condition of home, role strain, family support, case management

INTRODUCTION

Families where grandparents are the primary caregiver for their grandchildren are becoming more prevalent in the US as compared to 30 years ago [1, 2]. In 2012, 4.2 million US households were comprised of grandparents living with grandchildren [3] and 2.7 million grandparents were primary caregivers for their grandchildren under the age of 18 years old [4]. Caring for a child while in a later stage of life requires many adjustments on the part of the grandparent. For example, a grandparent who must tailor a home environment to meet the needs of a grandchild, especially one with a disability, can be challenging financially and emotionally, and thus, be a source of stress (see Figure 1). This, and other stressors can result in feelings of isolation and depression among these senior citizens [1, 5]. Also, grandparents are more likely to need to manage their own health conditions alongside their grandchildren's health; often times, these health conditions (hypertension, heart disease, diabetes, and arthritis) which are more likely to occur in older populations are chronic in nature, and thereby, require more frequent visits to healthcare providers, medications, and limit their mobility. Consequently, managing these chronic conditions along with the needs of their grandchildren, particularly if the children have disabilities, can negatively impact the health and wellbeing of all members of the household [6, 7]. In these situations, elderly primary caregivers have been found to neglect their own health in order to properly care for their grandchildren [7]. Grandparents, many of whom are on a limited and fixed income, must address the added financial burden associated with the care of their grandchildren with disabilities or chronic medical conditions. Costs tied to medical treatment or transportation to medical facilities [8] diverts funds from maintaining the home environment [9].

Innovative Solutions for Disadvantage and Disability (ISDD) is a not-for-profit organization, based in Atlanta, Georgia that supports children, with or at risk for disabilities, from low income, primarily minority and underserved communities [10]. They work with community leaders and support community-based participatory research that helps reduce health disparities among vulnerable children. Project GRANDD, a program of ISDD, uses a family-centered support model to specifically address the needs of grandparents who are the primary caregivers for their grandchildren with disabilities. Educational support, forum to share common experiences with other grandparents in similar predicaments, home visits by trained social workers, and appropriate referrals to legal and other necessary social service agencies are examples of the type of family-centered case management provided through Project GRANDD.

The impact of financial, physical, and mental stressors on the health of grandparents is an issue that deserves serious consideration. The purpose of Project GRANDD is to "break the cycle" of intergenerational disadvantage by reducing stress and improving health outcomes through family-centered case management (Figure 1). In this study, we examined the direct and indirect impact of family-centered case management offered through Project GRANDD

on enrolled grandparents' quality of life, using indicators of their perceived health benefit and the safety of their place of residence.

Figure 1. Potential risk factors for grandparents raising grandchildren with disabilities and the impact of Project GRANDD.

METHODS

This study is a cross-sectional survey of grandparents who were actively enrolled in a case management program offered through Project GRANDD.

Study Participants

Grandparents who were members of Project GRANDD and had at least one grandchild with a disability under their direct care were eligible to participate. Participants were required to be residents of the state of Georgia, speak and understand English, and live in a rented or owned property. Active members of Project GRANDD were defined as those grandparents who had consistent contact with program staff through calls, emails, and group meetings since joining the program. Inactive members of Project GRANDD were defined as those grandparents who had joined the program but did not have any further interaction with the program. The active/inactive distinction was made by the staff social worker in Project GRANDD [11].

Recruitment and Enrollment

Letters with information about the study and a notification that contact would be made by research staff were sent both through the US Postal Service and electronically to all members of Project GRANDD. Within 20 days of mailing, study staff telephoned all active and inactive members to inquire about participating in the study.

After informed consent was obtained from the phone call, study staff administered the survey questionnaire through personal phone interviews. The survey questionnaire included demographic information and was divided into two components: a) health survey explored grandparents' medical conditions which and b) home environmental survey assessed the participant's perception of home safety [12]. All information collected was entered into a relational electronic database [13]. A chart review of documents was also conducted incorporating completed intake forms at the time of grandparent entry into Project GRANDD, records of home visits made by the case manager or nurse, written logs of attendance at monthly grandparent support group meetings, any referrals made, and records of all phone contact. Information was collected, beginning at the point of entry into the program through the date of enrollment into the study.

Data Analysis

Standard frequency data (mean, range, and percentile) were determined for various characteristics describing participants. The independent variables consisted of the length of time the participant spent in Project GRANDD and the total number of resources received in the program (e.g., referrals, home visits, phone calls, monthly group meetings, and nurse visits). The dependent variables were self-reported health status, home environment condition status, and the composite score of the environmental survey. The composite score was created from a subset of ten questions taken from the 32-item questionnaire [12]. Odds ratios and corresponding 95% confidence intervals (CI) were calculated for health status, environmental status, and home environment improvement status. Multivariate logistic regression analysis was performed to assess the association between case management and perceived health and home conditions. Statistical analyses were conducted, using SAS Software package (SAS version 9.2) [14].

RESULTS

Of the 120 grandparents in Project GRANDD, 68 were active and 52 were inactive (see Figure 2). From the 68 active and 52 inactive members, 40 active and six inactive members were enrolled into the study. The average age of the grandparents in our study was 61.5 years. Of the 46 participants enrolled in the study, 97.8% [45] of the participants were female and 95.7% [44] of the participants were African-American (see Table 1). The average median household income reported was in the category of \$20, 000 - \$29,000; only one family reported a household income of greater than \$60,000. Seventy-six percent of grandparents reported at least one health condition: hypertension [24], stress [15], diabetes [12], and

hypercholesterolemia [6] (see Figure 3), while 11 grandparents reported having no chronic medical conditions. The average number of grandchildren per household was two (range: 1 – 7) (see Figure 4), and 15 grandparents reported caring for multiple grandchildren, with and without developmental disabilities. Of the 108 grandchildren, the most common disabilities reported among the grandchildren were: Attention Deficit Disorder (ADD), Attention Deficit Hyperactivity Disorder (ADHD) (38.9%), asthma (23.1%), behavioral disorders (23.1%), autism (18.5%), learning disabilities (18.5%), and developmental disorders (15.7%). Twenty-six (24.1%) grandchildren had no associated conditions and 38 (35.2%) had two or more (see Figure 5).

Figure 4. Number of grandchildren per grandparent.

Figure 5. Number of disabilities per grandchild.

Impact of Program

We looked at the association between length of time in Project GRANDD and the grandparent's health and home environmental score. The odds ratio for the health status, environmental status, and environmental composite score were 1.08 (95% CI: 0.98 – 1.28), 1.37 (95% CI: 1.05 – 1.78), and 0.99 (95% CI: 0.83 – 1.17), respectively (see Table 2). We also assessed the relationship between number of resources received in the program on grandparent's health and composite home environment and found that the odds ratio on health status, environmental status, and environmental composite score were 0.985 (95% CI: 0.906–1.071), 1.16 (95% CI: 1.047 – 1.283), 1.014 (95% CI: 0.931 – 1.105), respectively (see Table 3). We tested for confounding factors (length in the program and total number of resources = covariates) and none were found.

The average length of time grandparents were in the program was four years (range: 1 month – 15 years). With each year in the program, the odds of a perceived improved effect on the home environment increased by 1.37 (95% CI: 1.05 – 1.78). Health status improved by 1.08 (95% CI: 0.98 – 1.28) for each additional year in the program. The average number of resources (i.e., referrals, home visits, phone calls, monthly group meetings, nurse visits) received by the grandparents while in the program was eight (range: 0 – 22). The odds of a perceived environmental home improvement increased by 1.16 (95% CI: 1.047 – 1.283) for each additional resource received by grandparents. Our data also showed that 43.5% and 39% of the grandparents reported a health improvement and home improvement when asked directly.

DISCUSSION

Grandparents who are the primary caregivers for their grandchildren are disproportionately women of color [15]. In our study, we also found a majority of the participants who self-identified as African-American females with the average age of 62 years. It has been postulated that historically, African American families who were living in impoverished conditions, tended to live with extended family members in order to pool resources, which included financial means and caregiving roles [16]. This finding may account for why we have such a significant number of grandparents who serve as the primary caregiver of their grandchildren, often for more than one.

Caring for a child with a disability or chronic medical condition is associated with increased stresses, however, perceptions of stress differ among caregivers, depending on the levels of stress, the number of stressors and the experiences, outlook and support that each individual has [9, 15]. Only 32 percent of grandparents in our study reported experiencing stress; we did not explore the reason why some grandparents reported stress and others did not, but other studies also show conflicting responses when grandparents are put into the position of caring for their grandchildren [9, 14, 17, 18]. One possibility for the discrepancy may be related to the observation that some grandparents felt invigorated in this role as primary caregiver, thereby, giving them a sense of purpose, while others may have felt burdened and isolated by having such a large responsibility [19]. There are clearly significant personal, experiential, emotional and practical reasons as well as the phenomenon of

resilience that ought to be considered, when accounting for how much ‘stress’ is added by serving as the primary caregiver of a grandchild.

Caregivers of children with disabilities benefit from practical and concrete services such as stipend programs and respite care [15]. However, in our study, the length of time and total number of resources received in the program showed no statistically significant positive impact on the perceived health status or the environmental composite score. We did observe the relationship between supportive case management and the grandparents’ perception of improved health and home environment. This perceived improvement on the home may have occurred because the grandparents received assistance through referrals and stipends. Referrals made through case management enabled repairs to be done on the home itself, with companies who provided repairs at reduced costs. A consistent support provided to grandparents was the regular opportunity for grandparents to share their experiences with other grandparents in similar situations. This “support group” might have contributed as an indirect benefit to perceived improved health by participating grandparents. This allotted time to share created a sense of community among these grandparents and may have reduced feelings of isolation which may have reduced their overall stress levels. Additional studies are needed to further explore the relationship between family-centered case management and benefits to improved health and home conditions.

Limitations

Our study used a cross-sectional design and we were limited in our findings. We were unable within the time frame to conduct a case control study, which may be able to ascertain more clearly the impact of case management on specific health outcomes of grandparents and their grandchildren. In our study, we had no comparison control group to assess the true impact of the interventions. We were also limited by findings based on self-reports given by participants. During the recruitment process prior to enrollment, some grandparents declined to participate reporting that they had limited free time and hectic schedules, so our findings were limited by selection bias—only grandparents who could set aside time for the study were able to join, thereby excluding possible valuable information from those unable or unwilling to participate. There may have been a recall bias present as well, since participants were asked to remember situations and events that occurred prior to joining Project GRANDD in order to get a before/after effect when collecting data which would require a more accurate recall of events in the distant or recent past.

FUTURE DIRECTIONS

Moving forward we recommend a prospective case-control study to more clearly and accurately evaluate the impact of the program on the health and well-being of the grandparents and their grandchildren, as well as on their home environment. Greater focus should be on the nature of resources each grandparent receives through Project GRANDD, in order to identify the resources with the greatest beneficial impact on their lives. A well-designed home environment survey could be used to shed light on the living conditions of the

families. The information used could help to enhance relationships between the grandparents, their landlords and other service agencies. Social workers who work directly with the elderly could then use the data to evaluate the needs of the people they serve and advocate for improved living conditions. Researchers are in the position to shed light on the nuanced experience of multigenerational families and suggest interventions that aid in healthy family dynamics. We feel that, in the US, priority should be placed on helping grandparents who raise grandchildren, especially grandchildren with disabilities in order to “break the cycle” of intergenerational disadvantage and reduce the likelihood of disabilities and health disparities.

ACKNOWLEDGMENTS

The authors would like to thank the members of Project GRANDD who participated in the study; they played an integral role in the research conducted by the research team. We would like to show gratitude to Ms. Laura Wells, Ms. Rainie Jueschke, and Dr. Leslie Rubin from ISDD who gave us access to the case reports necessary for the study. There is also deep gratitude to Morehouse School of Medicine and the Clinical Research Center for ensuring the integrity of the study and the safety of the participants. Praise is also given to Mr. Aneeq Malik for aiding in the recruitment process. We are truly grateful for all of the institutions and people listed who contributed to making this study come to fruition.

Chapter 19

ADDRESSING SOCIAL DETERMINANTS OF HEALTH AT A FEDERALLY QUALIFIED HEALTH CENTER

***Caroline Hensley*, MPH, Avinash Joseph, BS, Shivam Shah, BS,
Christy O'Dea, MD and Kelley Carameli, DrPH***

Department of Environmental Sciences,
University of Cincinnati College of Medicine, Cincinnati, Ohio, USA

ABSTRACT

Social determinants of health (SDH) are the external conditions in which a child and his or her family live, work, learn, and play that can impact quality of health. The impact of SDH is often negative when a child is living in poverty. We utilized the HealthBegins Upstream Risks Screening Tool to evaluate children and families attending a low-income clinic in Southern Ohio/Northern Kentucky. Results were used to connect the children and their families to local community resources to address the SDH areas of greatest need. Population data on these children and their families informed the screening process and reinforced the need for this non-clinical, social service. Undergraduate and graduate students were effective in obtaining information to address SDH in the primary care setting.

Keywords: social determinants of health, federally-qualified health center, students, asthma, public health

INTRODUCTION

Margaret Whitehead, DBE was one of the first to establish inequity in health as unfair and unjust [1]. In cities across the United States health inequity can result in a life expectancy gap between the rich and the poor of up to fifteen years [2]. Limited access to medical care

* Corresponding Author's Email: henslecg@mail.uc.edu.

and unhealthy behaviors have traditionally been accepted as causes for poor health outcomes [3]. However, limited access to medical care and unhealthy behaviors only account for a portion of poor health outcomes [4]. A broader explanation for health disparities may be attributed to a person's social environment, or "the circumstances in which people are born, grow up, live, work, and age" as the social determinants of health (SDH) [5]. Children living in poverty with its associated SDH, are at greater risk for adverse health outcomes such as asthma and are less likely to receive consistent preventive care (e.g., Well-Child Checks) than children from families with high incomes [6-8].

Pediatric primary care providers have long provided primary prevention, and the screening necessary for secondary prevention [9] with a variety of guidelines and screening tools to address SDH in the primary care setting [10, 11]. It is currently recommended that SDH screening tools be used for families of pediatric patients during well-child checks and paired with education on available community resources [12, 13]. Despite the growing evidence of the important role of SDH in child health, addressing SDH is not a standard of care and does not systematically occur in the primary care setting. Common barriers to addressing SDH include minimal financial incentive, a lack of professional awareness and training, limited familiarity with screening tools, and disconnection with community resources to address SDH [11, 14].

Figure 1. Study purpose: Breaking the cycle at five points.

The quality improvement project assessed in this paper explored the process of systematically screening pediatric patients and their families for SDH risks within a federally qualified health center (FQHC) clinic serving Southwestern Ohio/Northern Kentucky. FQHC care sites provide health care service regardless of the client's ability to pay; largely serving patients in households with income at or less than the 200% poverty level (90% of FQHC clients) [15]. FQHC patients, particularly children, are at the greatest risk for negative physical and social/emotional outcomes due to SDH. Incorporating regular SDH assessment and support into pediatric FQHC appointments is one strategy for "Breaking the cycle" in health disparities among low-income populations. This project sought to affect the SDH cycle at these points: compound risk factors, personal characteristics, environmental risk factors, environmental characteristics, and health risk factors (see Figure 1).

METHODS

Data Source: Our quality improvement project focused on pediatric patients and families attending a primary care clinic within a FQHC in Southwestern Ohio between January and April 2016. As the project's intent was to improve current clinic operations, the FQHC did not require IRB approval for this quality improvement assessment.

Patients and families who registered at the clinic were invited into a side consultation room prior to their clinic appointment to learn about the new operational screening. They met with one of four volunteer students; undergraduates and graduates who were recruited and trained in Health Insurance Portability and Accountability Act (HIPAA) regulations, cultural competency, and professionalism. The student described the screening, its potential benefit to the patient and family, and its use for improving clinic services. The pediatric patients and families who chose to participate were screened immediately, and those who chose not to participate returned to the clinic waiting room for their regular clinic visit. Regardless of screening participation, all patients saw the clinic provider per their scheduled appointment.

The screening lasted approximately 6 minutes. Overall, 114 families participated out of 128 who were approached. Reasons given for non-participation included distrust, disinterest, or lack of time. The small scale of the project allowed the assessment team to learn from the screening process, and understand the time investment needed to provide patients and families with SDH screening and support.

Data Tools

The “HealthBegins’ Upstream Risks Screening Tool” was selected as the pilot screening tool of SDH for this study by the clinical staff at the FQHC (see attachment 1). It was administered by the trained students through conversation with the participants and scored immediately for use in the patient’s clinic appointment.

The tool included 26 questions grouped into 14 different social need categories: education, employment, social connection and isolation, physical activity, immigration status, financial strain, housing insecurity, food insecurity, dietary pattern, transportation, exposure to violence, stress, and civic engagement (see Table 1). Within these categories, previously established criteria were used to determine whether or not the patient was positive for a social risk on a given question.

Table 1. Pediatric patients and families identified at-risk by screening procedure

Pediatric Patients and Families Screened At-Risk by Categories	
# Screened At-Risk with 0 < Positive Categories	111 (97.4%)
# Screened Not At-Risk with 0 > Positive Categories	3 (2.8%)
Total (N)	114
Pediatric Patients and Families Screened At-Risk by Questions	
# Screened At-Risk with 0 < Positive Questions	113 (99.1%)
# Screened Not At-Risk with 0 > Positive Questions	1 (0.9%)
Total (N)	114

Each question was categorized as a binary variable (i.e., 1 if the patient was at-risk and 0 if the patient was not at-risk). These variables were then summed to assess each patient’s total social need score, ranging from 0-26. Additional social need sub-scores were summed within each social need category. If 50% or more of the questions within a category had a score of 1, then the whole category received a score of 1, for a potential score range of 0-14 across the 14 categories.

The second tool involved a community resources guide with a one-page educational handout. Following the SDH assessment, at-risk results were cross-walked to a community resources guide built to identify local Southwestern Ohio/Northern Kentucky agencies and programs that addressed the social needs covered by the screening tool. The guide listed for each supporting program or agency: resource eligibility requirements, contact information, and any additional access information. The guide was made available during the in-office consult to the screened participants, and published online (www.letschangeourcity.org). Non-screened patients and families were not directly notified of the guide’s online availability at this pilot improvement stage, but could have accessed it directly on their own. For those receiving the educational handout, it listed the community resources reflective of the patient’s identified social need. Patients and families were offered assistance in making contact with the referred community resource(s), as well as help in accessing other supportive services not listed in the community resources guide.

Data Measures

The operational utility of the quality improvement screening used three measures: SDH, visit type, and asthma diagnosis. SDH was measured using the overall (0-26) and sub-category (0-14) scores from the HealthBegins’ Upstream Risks Screening Tool. Visit type was tracked by the clinic appointment as child check-up [1] or acute [2], to determine if patients’ SDH risks varied with whether the clinic visit was planned or unplanned. Asthma diagnosis was tracked by the patient’s medical chart as positive [1] or negative [0] (see Table 2). Asthma was selected as a key variable because the literature suggests it is a physical health condition with higher prevalence among children in poverty; the predominant population attending our FQHC clinic [7].

Table 2. ICD-10 codes considered positive diagnosis for asthma

ICD-10 Code	Description
J45.2x	Mild Intermittent Asthma
J45.3x	Mild Persistent Asthma
J45.4x	Moderate Persistent Asthma
J45.5x	Severe Persistent Asthma
J45.90x	Unspecified Asthma
X = 0	Uncomplicated
X = 1	With Exacerbation
X = 2	With status

Data Analysis

Our operational analyses used SAS 9.4 for logistic regression models. SDH risk (overall, sub-category) was independently compared against visit type and asthma diagnosis using two-tailed T-tests.

Table 3. Summary statistics for analysis variables

Question	Category	Variable	N	N (%)
1A	Education	Highest Ed	113	27 (23.9%)
1B	Education	Highest Deg	89	63 (70.8%)
1C	Education	Child Prob	100	21 (21.0%)
2	Employment	Employment	110	29 (26.4%)
3	Social Connection & Isolation	Marital	113	80 (72.7%)
4A & 4B	Social Connection & Isolation	Social	112	11 (9.8%)
4C	Social Connection & Isolation	Faith Year	113	64 (56.6%)
4D	Social Connection & Isolation	Club Year	113	89 (78.8%)
5A & 5B	Physical Activity	Exercise Week	110	73 (66.4%)
6	Immigration	Immigration	113	9 (8.0%)
7A	Financial Strain - Overall	Financial Strain	113	28 (24.8%)
7B	Financial Strain - Overall	Financial Basics	113	47 (41.6%)
8A	Housing Insecurity	Housing	112	2 (1.8%)
8B	Housing Insecurity	Housing Quality	113	13 (11.5%)
8C	Housing Insecurity	Housing Move	112	2 (1.8%)
9	Food Insecurity	Food Security	113	1 (0.9%)
10A	Dietary Pattern	Fruit Day	113	44 (38.9%)
10B	Dietary Pattern	Veggie Day	113	97 (85.8%)
11	Transportation	Transport	107	12 (11.2%)
12	Exposure to Violence	Safety	112	18 (16.1%)
13A	Exposure to Violence	Emotional Abuse	112	13 (11.6%)
13B	Exposure to Violence	Fear Partner	112	7 (6.3%)
13C	Exposure to Violence	Rape	112	6 (5.4%)
13D	Exposure to Violence	Physical Abuse	112	5 (4.5%)
14	Stress	Stress	112	47 (42.0%)
15	Civic Engagement	Help Vote	112	9 (8.0%)
-	-	Acute	114	65 (57.0%)
-	-	Asthma	108	22 (20.4%)

RESULTS

Of the 114 patients completing the SDH screening tool, 97.4% were identified as being at-risk for at least one of the 14 SDH tool sub-categories, while 99% were found to be at-risk for at least one of the 26 screening questions (see Table 1). The screening tool items incurring the highest percentage of at-risk SDH scores represented the categories of dietary pattern, social connection and isolation, and physical activity (see Table 3).

Log-risk models of overall SDH screening scores were not significant by appointment type (Wald Chi-square test statistic = 1.50, $p = 0.21$) or asthma diagnosis (Wald Chi-square test statistic = 1.3, $p = 0.25$). The same non-significance was found for SDH sub-category scores (appointment type: Wald Chi-square test statistic = 1.16, $p = 0.28$; asthma: Wald Chi-square test statistic = 0.34, $p = 0.56$). Still, mean score testing of overall and sub-category

SDH scores by appointment type showed that acute care appointment patients had higher SDH risks, compared to well-child check patients; although the difference was not significant (overall: unpooled mean difference = -0.74, $t = -1.26$, $p = 0.21$; sub-category: unpooled mean difference = -0.35, $t = -1.07$, $p = 0.29$). Likewise, mean score testing of overall and sub-category SDH scores by asthma diagnosis showed higher SDH risks for positive compared to negative diagnoses; although the difference was not significant (overall: unpooled mean difference = -0.87, $t = -1.26$, $p = 0.22$; sub-category: unpooled mean difference = -0.24, $t = -0.63$, $p = 0.53$).

DISCUSSION

Our assessment stems from a quality improvement project that examined the systematic screening of pediatric patients and their families for SDH risks within a FQHC. The screening tool effectively captured the estimated risk levels of our FQHC families showing the majority (97%) of our pediatric patients at-risk for at least one SDH. The most frequent SDH issues were dietary pattern, social connection and isolation, and physical activity.

In the literature, these findings are not uncommon with SDH experiences reported by persons in poverty; particularly a greater risk for obesity given poor dietary options and lower physical activity [16]. Although variations exist, common barriers to proper nutrition and physical activity for low income individuals often include limited flexible time in travelling to food stores or for exercise), and poor access to healthy food areas or safe green spaces [17]. For issues of social isolation, limited social support is linked to poverty, as it limits one's access to supportive resources used in sharing burdens around childcare, finances, or stress [18].

Our assessment also found observable, but non-significant, differences in SDH scores by appointment type and asthma diagnosis. As expected, SDH risks were greater for pediatric patients and their families seeking acute care, and for pediatric patients with asthma and their families. These findings also align with the current literature where children in poverty are less likely to receive consistent preventative care [8], which may delay timely diagnosis or treatment of chronic conditions, including asthma. Additionally, housing conditions, smoke exposure, and traffic air pollution are all environmental conditions that contribute to asthma and are related to poverty [7, 19].

Finally, our quality improvement assessment suggests that systematic SDH screening of pediatric patients within a clinic environment is feasible and, anecdotally, beneficial for both the patient/families and the clinic provider. We used a trained cadre of four student volunteers to administer the screening tool and refer patients/families to appropriate social services. We believe that the patients and families benefited from the time, talent, and energy of the SDH screening, as perceived by patients' informal expressions of appreciation toward the new information on their SDH risks and local resources, and our provider reflecting on an increased confidence in addressing SDH issues.

Still, there are potential limitations in our process improvement findings. For example, fear of adverse consequences may have limited participation and led to underreporting of social needs. In the future, we may consider a standard form for parents to complete prior to the visit or use of self-guided technology to collect SDH information; strategies that have had

successful application in other primary care settings [20, 21]. We also do not have information on whether participants who received the educational handout used it to access community resources tailored to their SDH needs. It would be interesting to reach out to these families to assess the resource's utility and limitations, as well as to reach out to families that missed their appointments to perform the screening by phone. It is possible that continuing SDH barriers, including transportation, clinic hours, or child care issues, limits the resource or health care utilization for much of our patient population. However, these issues were not explored in our assessment.

Going forward, it is apparent that the majority of families at our FQHC had unmet social needs. The primary care setting is an ideal opportunity to screen for and identify SDH and match families in need with appropriate community resources. Substantial organizational and community coordination is necessary to ensure ethical and effective screening [22]. Stronger and more direct primary care-community resource partnerships would provide greater opportunity for success in addressing SDH and matching families to community resources for long-term support [22, 23]. Further training of alternative workforces, such as volunteer students, clerical staff, or intake workers to address SDH has potential to make SDH screening cost-effective despite limited financial incentive or reimbursement.

Our work also indicates that implementing a brief screening tool into already busy clinic operations is feasible, and may likely improve care coordination between providers and at-risk families, improve health outcomes for pediatric FQHC patients, and reduce SDH-related disparities.

Regardless, policy makers, legislators, and individual citizens must be educated as to the influence of SDH on adverse health outcomes and together should develop implement effective strategies for screening and for connections with resources.

ACKNOWLEDGMENTS

This project and the preparation for this paper were supported by Crossroad Health Center, University of Cincinnati Department of Environmental Health, and the "Break the cycle" program through the Southeast Pediatric Environmental Health Specialty Unit and Innovative Solutions for Disadvantage and Disability Sustainability Initiatives at Emory University.

APPENDIX

Upstream Risks Screening Tool

"Everyone deserves the opportunity to have a safe, healthy place to live, work, eat, sleep, learn and play. Problems or stress in these areas affect health. We ask our patients about these issues because we may be able to help."

Date of screening: ____/____/____

What's your name? First: _____ Last: _____	What's your date of birth? ____/____/____
---	--

1. Education

- a. What is the highest level of school you have completed?
 - i. Elementary school
 - ii. High school
 - iii. College
 - iv. Graduate / Professional school
- b. What is the highest degree you earned?
 - i. High school diploma
 - ii. GED
 - iii. Vocational certificate (post high school or GED)
 - iv. Associate's degree (junior college)
 - v. Bachelor's degree
 - vi. Master's degree
 - vii. Doctorate
- c. Are you concerned about your child's learning, performance, or behavior in school?
 - i. Yes
 - ii. No
 - iii. Not applicable

2. Employment

- a. Choose one of the following. Which best describes your current occupation?
 - i. Homemaker
 - ii. Employed full-time
 - iii. Employed part time
 - iv. Employed, but on leave for health reasons
 - v. Employed but temporarily away from my job (other than health reasons)
 - vi. Unemployed or laid off 6 months or less
 - vii. Unemployed or laid off more than 6 months
 - viii. Unemployed due to disability
 - ix. Retired from my usual occupation and not working
 - x. Retired from my usual occupation but working for pay
 - xi. Retired from my usual occupation but volunteering

3. Social Connection & Isolation

- a. What is your marital status? Check one.
 - i. Married
 - ii. Living with partner
 - iii. Widowed
 - iv. Divorced
 - v. Separated
 - vi. Never married

4. Social Connection & Isolation

- a. In a typical week, how many times do you talk on the telephone with family, friends, or neighbors?
 - i. Number of times per week _____
- b. How often do you get together with friends or relatives?
 - i. Number of times per week _____
- c. How often do you attend religious or faith-based services?
 - i. Number of times per year _____
- d. How often do you attend meetings of the clubs or organizations you belong to?
 - i. Number of times per year _____

5. Physical Activity

- a. On average, how many days per week do you engage in moderate to strenuous exercise (like walking fast, running, jogging, dancing, swimming, biking, or other activities that cause a light or heavy sweat)?
 - i. Days per week _____
- b. On average, how many minutes do you engage in exercise at this level?
 - i. 0
 - ii. 10
 - iii. 20
 - iv. 30
 - v. 40
 - vi. 60
 - vii. 90
 - viii. 120
 - ix. 150 or greater

6. Immigration

- a. Do you have concerns about any immigration matter for you or your family?
 - i. Yes
 - ii. No

7. Financial Strain

- a. Do you ever have problems making ends meet at the end of the month?
 - i. Yes
 - ii. No
- b. How hard is it for you to pay for the very basics like food, housing, medical care, and heating? Would you say it is:
 - i. Very hard
 - ii. Somewhat hard
 - iii. Not hard at all

8. Housing Insecurity

- a. In the last month, have you slept outside, in a shelter, or in a place not meant for sleeping?
 - i. Yes
 - ii. No

- b. In the last month, have you had concerns about the condition or quality of your housing?
 - i. Yes
 - ii. No
- c. In the last 12 months, how many times have you or your family moved from one home to another?
 - i. _____

9. Food Insecurity

- a. Which of the following describes the amount of food your household has to eat?
 - i. Enough to eat
 - ii. Sometimes not enough to eat
 - iii. Often not enough to eat

10. Dietary Pattern

- a. How many pieces of fruit, of any sort, do you eat a typical day?
 - i. _____ pieces/day
- b. How many portions of vegetables, excluding potatoes, do you eat on a typical day?
 - i. _____ portions/day

11. Transportation

- a. How often is it difficult to get transportation to or from your medical or follow-up appointments?
 - i. Does not apply
 - ii. Never
 - iii. Sometimes
 - iv. Often
 - v. Always

12. Exposure to Violence

- a. Do you have concerns about safety in your neighborhood?
 - i. Yes
 - ii. No

13. Exposure to Violence

- a. Within the last year, have you been humiliated or emotionally abused in other ways by your partner or ex-partner?
 - i. Yes
 - ii. No
- b. Within the last year, have you been afraid of your partner or ex-partner?
 - i. Yes
 - ii. No
- c. Within the last year, have you been raped or forced to have any kind of sexual activity by your partner or ex-partner?
 - i. Yes
 - ii. No

- d. Within the last year, have you been kicked, hit, slapped, or otherwise physically hurt by your partner or ex-partner?
 - i. Yes
 - ii. No
- 14. Stress
 - a. Stress means a situation in which a person feels tense, restless, nervous, or anxious, or is unable to sleep at night because his/her mind is troubled all the time. Do you feel this kind of stress these days?
 - i. Not at all
 - ii. A little bit
 - iii. Somewhat
 - iv. Quite a bit
 - v. Very much
- 15. Civic Engagement
 - a. Would you like help registering to vote?
 - i. Yes
 - ii. No

Chapter 20

HEALTH VULNERABILITIES OF UTAH'S IMMIGRANT CHILDREN: BREAKING THE CYCLE

ABSTRACT

The health-related vulnerabilities of immigrant children are numerous, but information related to their needs is limited, especially in new immigrant destination states like Utah. In order to examine these vulnerabilities, this study incorporates responses from a variety of social service agencies that offer a broad range of health services for immigrant and refugee populations. Semi-structured qualitative interviews were conducted with sixteen respondents (N = 16) to elaborate on the health-related vulnerabilities of immigrant children and the specific practices that have been developed to address them. The respondents identified gaps in the medical system faced by immigrant children and outlined general health-related trends faced by the group as a whole. These social service providers were also familiar with a wide range of strategies that have been employed in an effort to “break the cycle” of vulnerabilities faced by immigrant children in Utah. The respondents specifically noted that the vulnerabilities to which the children of unauthorized immigrant children are exposed are fundamentally different than those faced by refugee children. This difference highlights the need for unique solutions for each group of children.

Keywords: health vulnerabilities, immigrant health, healthcare services, social services

INTRODUCTION

It is difficult to imagine a more vulnerable population than children of immigrants. They face numerous environmental and health-related challenges, including low-quality housing, transient lifestyles, and limited provision of legal rights and healthcare services. They and their parents experience unique cultural, linguistic, and transitional difficulties on a daily basis. While there are various types of immigrants, this project emphasizes the vulnerabilities faced by the children of undocumented immigrant families and those faced by the children of refugee families. An undocumented immigrant in the United States is “a foreign national residing in the United States without legal immigration status” [1]. A refugee is “a person who is unable or unwilling to return to their country of nationality because of persecution or a well-founded fear of persecution... the practice of accepting such refugees is that of offering political asylum” [1]. The term “immigrants” will be used in this paper for findings that describe both of these groups.

According to existing literature, many immigrant children form part of the “undeserving poor”: a demographic that is perceived by the majority population as being undeserving of socially-provided services [2]. They also face many vulnerabilities such as poverty, low English proficiency, mental anguish, and availability of only episodic health care [3-6]. All of these issues result in rates of poor health for immigrant children that are more than twice as high as those of native children [7]. For undocumented immigrant children, the situation is further compounded by the ever-present fear of deportation and family separation due to the family’s precarious legal status [3]. While the refugee population does not face the same legal barriers as the unauthorized population, parents and their children may carry lingering stress from circumstances faced in leaving their home country and still face many challenges in attempting to access health care. They face linguistic and cultural difficulties that make it difficult for refugees to navigate the complicated healthcare system of developed nations. A 2015 study found that refugees in Utah have “only a very basic understanding of how insurance and healthcare function” [8].

The impact of these differing vulnerabilities is especially powerful in states like Utah, where the presence of immigrant families is relatively new. Utah is a historically homogeneous state, with a traditional white majority and a conservative constituency. From 1990 to 2013, however, the percentage of foreign-born Utah residents more than doubled in size from 3.4% to 8.2% [9]. Based on 2010 census data, the Hispanic population alone grew from 201,000 to 358,000, a 78% increase in the last decade making them the fastest growing minority group in Utah [10]. Currently about 56% of immigrants in Utah are documented (including refugees) and 44% are undocumented [11]. This drastic change in the state’s demographics has had a variable impact on state politics.

Regarding immigration, the rhetoric of Utah decision makers vacillates between welcoming and condemning. In 2010 almost every political, economic, and religious leader in the state banded together to sign a document entitled the Utah Compact, which advocated for the humane treatment of unauthorized immigrants. The document represented a statewide concern for the wellbeing of immigrant families and identified Utah as a pioneer in the national immigrant debate. Utah’s governor, Gary Herbert, was the only Republican governor who did not reject acceptance of Syrian refugees into his state in the aftermath of the Paris attacks in February 2016 [12]. Today, Utah takes in roughly 1,100 refugees annually from

various countries including Burma, Somalia, and Iraq [13]. Various state policies, however, take a punitive stance toward immigrant families despite this compassionate rhetoric. Such policies include SB-81, which denies funding to social service agencies that fail to prove that their client bases are legal. The law effectively denies any state funds to unauthorized immigrants [11].

This inconsistent policy context provides an ideal backdrop in which to examine the health vulnerabilities of immigrant children. Developed states and nations all over the world are, like Utah, struggling to determine how best to respond an influx of immigrants. This project contributes to that ongoing discussion by asking the following questions: “What are the health vulnerabilities of Utah’s immigrant children?” and “Are there difference in vulnerabilities between the children of refugees and the children of undocumented immigrants?” Based on our literature review, we hypothesized that the health vulnerabilities faced by immigrant children in Utah would be greater than those faced by the general public and that they would face significant barriers to accessing health-related services. We further hypothesized that the vulnerabilities faced by undocumented immigrant families would be different than those faced by refugee families and thus that unique solutions would be required to serve each population.

METHODS

While overarching trends in immigrant health are well documented, a relatively small number of people are privy to information related to the medical needs of specific enclaves of immigrant families. Social and medical service providers based in states and communities often have the greatest appreciation for the vulnerabilities faced by the groups that they serve. Our study was designed with this understanding in mind.

The study consisted of sixteen semi-structured interviews with a variety of social service agencies that offer a broad range of health services for immigrant and refugee populations. Participants were selected via criterion and snowball sampling methods. We generated our original contact list using information from the public domain on clinics and other social services within Utah working directly with immigrant populations. Once the initial participants were selected and interviewed, we asked them to identify additional respondents who might have insights related to immigrant vulnerabilities in the state. Every participant directed us to other organizations, many of which were not well known to the public. The study’s participant pool thus represents large organizations with an established web presence as well as grassroots entities known only to other professionals in the field. Of the sixteen participants, ten occupied management-level positions in their organizations and six worked directly with immigrant and refugee populations on a regular basis. Those in management positions (often executive directors) had many years of experience with their organizations and were thus able to discuss overarching trends in immigrant or refugee care. The direct-care workers offered intimate perspectives on the daily lives of immigrant families and their efforts to access health services. The pool of participants also differed by the population served by the respondent’s organization. Six offered services exclusively to refugee populations, two offered services only to undocumented immigrant populations, and eight offered services to both groups. The combined responses of these overlapping groups

illuminated the scope of the vulnerabilities into which Utah's immigrants fall and provided insight into the range of solutions that are currently being used to break that cycle.

The interview questions consisted of four main categories, all of which invited participants to outline differences between vulnerabilities faced by undocumented immigrants and those faced by refugees. First, we asked general information about the participant's organization to obtain an understanding of where they fit into the hierarchy of the institutions and what health services were offered to immigrants at their facilities. Second, we asked participants to identify the health vulnerabilities of immigrant children served by their organization. Third, we asked if there were any barriers that immigrant children faced in attempting to access health care services. Finally, we asked participants to report any successes by their agency in addressing immigrant vulnerabilities and their thoughts on future actions that could be taken by the agency or the government to further alleviate these vulnerabilities. The interviews lasted between 20-40 minutes. Fifteen of the sixteen participants consented to have their interviews recorded; their interviews were transcribed to ensure fidelity to the responses of our interviewees. Extensive interview notes were taken for the participant who preferred not to be recorded.

The interview process was discontinued when participants began to consistently refer our team to organizations with whom we had already spoken and when we began to hear repeated themes and few new insights across interviews. The interview notes and transcripts were then qualitatively analyzed to identify trends among the responses. These trends are explored in the following section.

RESULTS

Our results fall under four main categories: health vulnerabilities of immigrant children, health-related barriers faced by immigrants, barriers for service provision faced by agencies and solutions that had been or could be employed to address these barriers.

Health Vulnerabilities

When asked about specific health-related vulnerabilities faced by immigrant children, participants reported various similarities between the children of refugees and the children of undocumented immigrants. One of the most commonly referenced health issues that affected both groups was low dental health. Many participants said that it was difficult to help immigrant families take the health of their children's teeth seriously, given that it rarely represented an urgent need and was often not included in immigrant insurance plans, if they had any insurance at all. These dental health issues are exacerbated by distrust that immigrants have for tap water, which is fluoridated in the United States and thus has the capacity to improve dental health. One interviewee, in reference to the fact that the tap water in many less-developed countries is not potable, said that "the water [from the tap] is perceived as unclean and so they don't want to drink out of the faucet." This lack of trust excludes immigrant children from the benefits of the fluoridated public water. Immigrant children, given their life in often low-income homes and neighborhoods, are also exposed to a

wide variety of environmental health hazards, especially lead exposure. Speaking about the dangers of lead exposure, one interviewee said “[it] will go into the brain and actually permanently short-circuit parts of the brain...their IQ drops oftentimes by ten percent; they have a variety of behavior issues.” In fact, the American Academy of Pediatrics reports that that “no amount of lead exposure is safe for kids” [14]. Mental health issues such as anxiety and depression also affect both immigrant groups. The mental health issues reported were often related to the trauma of moving to a new country. This finding matches the underlying trends in immigrant health discussed in the literature review. Finally, many participants pointed to transition-related symptoms, such as respiratory difficulty, and skin ailments that affected undocumented immigrants and refugees equally. These transition-related symptoms were often the result of elevation and atmospheric differences between Utah and the immigrants’ home countries.

While refugees and undocumented immigrants shared many health vulnerabilities, as discussed above, some vulnerabilities were specific to just one group. Participants reported that undocumented children faced much higher rates of obesity and pesticide exposure than either native-born children or refugee children. The regular pesticide exposure was due to the high rate of employment in the agricultural sector by undocumented immigrant parents. Refugee children, on the other hand, were more likely to be underweight or malnourished and have parasites upon arrival in the United States. These observations were attributed to the fact that most of them arrive in the U.S. after extended stays in refugee camps with little access to nutritious diets. Participants noted, however, that refugee families struggle to maintain a balanced diet even after having spent some months in the country. “All of a sudden,” one reported, “they [refugees] were able to go grocery shopping ... they're not even exposed to what the different foods in the grocery are.” This unfamiliarity with the resources provided in developed countries was a common theme among respondents: many health vulnerabilities faced by refugee children were the result of the “cultural illiteracy” of the refugee families.

Comparing Refugees and Undocumented Immigrants on Barriers to Health-Related Services

According to participants, both refugee and undocumented immigrant families have difficulty receiving health-related services due to the regularly scheduled operating hours of most clinics. Given various circumstances faced by immigrant parents, including low English proficiency, many of them work in positions that pay by the hour. This makes the decision to take time off to take a child to the doctor a difficult one. Participants explained that many immigrant families also have restrictive insurance plans because Utah is one of the 19 states that has not expanded Medicaid [15]. Given that many immigrant families fall within the low-income demographic of the state’s population, participants reported that this Medicaid restriction is particularly devastating to them. A previous study found that “the high costs and confusing nature of medical costs and insurance coverage [are] stressful issues for refugees” in Utah [8]. Even when affordable health-related services are available, however, immigrant families face a knowledge barrier in regards to health-related services: they often do not know what programs are available to them and their children. While services are available to them

in some cases, many immigrant families are unaware of where to find them and lack the language skills or social networks to learn more.

Interviews highlighted that some barriers to health-related services apply specifically to undocumented immigrant families, the greatest of which is fear. Many undocumented immigrant families fear that if they seek out medical services they will be forced to provide documentation that will reveal their non-legal status, potentially resulting in deportation and separation from the rest of their family. Participants reported that many services are available for this population that do not require any documentation, but the fear felt by undocumented families immobilizes many of them to the point that they do not receive even the treatments for which they are eligible. This phenomenon, among others, has resulted in a situation in which, according to one participant, “Utah has the worst rate of insurance for Latino children in the United States... 22 percent of Hispanic children don't have health insurance in Utah compared to 11 percent nationwide.”

Interviews revealed that other barriers to services are faced by refugee families to a larger degree than undocumented families. Participants indicated that refugees struggle when trying to access services due to their lack of familiarity with the United States' healthcare system and society in general. This lack of familiarity does not extend solely to the healthcare sector, but also incorporates transportation difficulties, literacy barriers, language skills, and limited social networks. A combination of these barriers has led to a significantly high “no show” rate for medical appointments made by refugees. One participant reported that this rate of refugee absences is as high as 50% at their clinic.

The differences in barriers faced by undocumented immigrant families and those faced by refugee families can largely be explained by what we have labeled the “fear / familiarity dichotomy” rather than a lack of cultural awareness of how the system works. Whereas many undocumented immigrant children lack access to healthcare given the fear that they face due to their non-legal status, many refugee children miss out on services because neither they nor their parents are familiar with the medical bureaucracy of a first-world country. The dichotomy was best illustrated by one participant, who said, “[Refugees] don't have the same fears as undocumented immigrants. [Undocumented immigrants] often fear applying for services due to the chance of deportation... [Refugees] often just don't know when or where to go for certain services. For instance, many will go to the ER for a simple cold. They just don't know how to navigate the medical system.”

Barriers to Health-Related Services Faced by Agencies

Interview participants also looked inward to their organizational efforts and identified some of the complications that they face in their attempts to provide services to immigrant children. Many reported a general lack of funding from the state and federal governments, low political will to serve immigrant families given Utah's history as a conservative state, immigrant housing checks being thwarted by landlords who refused to allow inspections of rented property, and issues with accessing the (often nonexistent) medical records of immigrants from their home countries.

For organizations that seek to provide services specifically for undocumented immigrants, the most common inhibitor was said to be the lack of state funding, which (due

to SB-81) is often tied to the agency's ability to prove that its clients are legal residents. Once an agency finds out that a client is undocumented, the range of services that it is able to offer and referrals that it is able to make narrows dramatically. Aside from the difficulties associated with procuring state funding, organizations that serve undocumented immigrants even struggle to acquire funding or grants from private donors. Many such grants come with "strings attached" that indicate which groups of people are eligible to receive services and which are not. Undocumented immigrant populations are regularly excluded from these eligibility pools for private grants. Many participants also reported that various would-be volunteers with their organization had indicated that they would be unwilling to serve undocumented immigrant families. These responses highlight the reality of undocumented immigrant families falling within the "undeserving poor" category, as described above, and also illustrate the indifference that some of Utah's conservative constituency feels towards this population.

Participants from refugee-oriented organizations reported that their biggest issue with funding is the expiration date associated with newly arrived refugee clients. After these refugees reach a certain threshold of time spent in the U.S., often at eight months, many of the funding opportunities that were available to them when they first arrived are removed because they are no longer considered "recent arrivals." This loss of funding severely restricts the agencies' abilities to assist refugee families in attaining long-term stability, even though they would like to do so. Another problem specific to refugee-oriented organizations is associated with the high refugee "no show" rate for medical appointments, which was referenced above. High refugee "no show" rates indicate a loss of revenue for clinics that rely on the income derived from the steady flows of patients through fee-for-service reimbursement. Also, many refugee-oriented organizations have struggled to find interpreters with an adequate medical vocabulary to serve a new influx of refugees from places like Somalia, Syria, and Burma. This dearth of medically-trained interpreters restricts the abilities of many organizations to effectively address the health-related vulnerabilities of their refugee clients.

Solutions: Breaking the Cycle

The combined influences of fear, cultural unfamiliarity, low English proficiency, low income, reluctant donors, and many other factors described above contribute to a destabilizing cycle of vulnerabilities that results in poor access to health-related services for immigrant children. Figure 1 shows the array of health disparities found in this study of Utah's immigrant children.

While the prospects for healthy immigrant families might appear dismal given the existence of this cycle, nearly all of our respondents reported that they and their organizations had found successful ways to navigate the complicated social, political, and economic difficulties associated with immigrant health in order to effectively serve their disadvantaged clients. The following is a list of creative solutions that Utah's organizations are *currently* using to help immigrant families break out of this cycle of health-related vulnerabilities (see Figure 1):

- Many immigrant-oriented agencies have developed informal partnerships with other health providers and refer their clients to the services provided by their partners. This practice effectively addresses the difficulties associated with the small social networks that many immigrants have when they first arrive and also enables agencies to advertise their services to a broader pool of potential clients.
- Various refugee-oriented organizations have adopted cultural education programs to help their clients learn to ride the bus, navigate a grocery store, or learn basic English. These programs help refugee families overcome their unfamiliarity with the complicated social dynamics in their new country of residence.
- Many organizations have identified unconventional yet practical locations in which they can advertise their services. Advertisements situated in churches, mosques, WIC clinics, preschools, ethnic restaurants, and other such places were particularly effective.
- One participant mentioned that her organization, aware of the fear that many undocumented immigrant families faced when arriving at a clinic to receive medical care, instructed its staff members to act like they worked for a private practice rather than a non-profit organization. The participant indicated that trust barriers dissolved if clients were treated with the respect and concern that are normally shown to full-paying customers.
- One refugee-oriented organization, hoping to expand its services to new immigrant populations, developed a creative way to hire culturally competent staff members who were invested in the community. The director of this organization went into the community and asked residents to identify a local leader who spoke both English and the language commonly spoken in the community, had a car and a cell phone, and was trusted by his/her neighbors. When such a person had been identified, this organization director simply approached the leader and hired the person on the spot, offering money if he or she would consent to acting as an intermediary between him (the director) and the community. This grassroots hiring strategy enabled this organization director to provide culturally competent services to many refugee communities about which he had very little personal knowledge.
- One particularly innovative solution involved the creation of a “Mobile Medical Clinic”—essentially a mobile home converted into a doctor’s office. Many of the services that immigrant families need are compacted into this portable clinic, which is then brought directly into immigrant communities. The Mobile Medical Clinic eliminates many of the barriers associated with low social networks, low access to public or private transportation, fear of straying too far from one’s community, and lack of familiarity with the bureaucratic atmosphere of a doctor’s office. Service providers working for the clinic are often able to work with immigrant families in their homes, making the patients feel more comfortable and also giving medical professionals an opportunity to examine their living conditions.

Participants were also asked about solutions to immigrant health vulnerabilities that they hoped could be instituted *in the future*. A list of their responses follows (see Figure 1):

- Various participants indicated that if Utah opted to expand Medicaid it would improve the wellbeing of the state's immigrant population dramatically. Some reported clients had moved to states where Medicaid had already been expanded in order to find more affordable services and insurance for their families.
- Other participants suggested that the expectations for newly arrived refugees be changed to include English education. The current system, according to the respondents, is focused on funneling newcomers directly into the labor market with no thought given to their long-term employment prospects. If English education were given priority over immediate job placement, they argue, newly-arrived refugees would be competitive to work in more lucrative industries that would enable them to pull out of the low-income demographic faster than they are currently able to do.
- Some agencies hope to circumvent the unavailability of medically trained interpreters by creating programs within their organizations to teach and/or hire staff members that speak the languages commonly spoken by their client base.
- One large-scale idea involved the creation of a multi-facility "Immigrant Care Campus": a plaza of services that would provide medical, housing, legal, educational, and other assistance for immigrant families in a single location. The participant raising this idea indicated that such a suite of services has been built into clinics in Phoenix, Arizona (affiliated with the University Medical Center) and in Boise, Idaho (affiliated with St. Alfonso's Hospital) with remarkable success.

DISCUSSION

Many of the results of this study speak for themselves. The health-related vulnerabilities faced by immigrant children in Utah are undeniably real, as are the barriers that are faced by immigrant families and medical providers. Many of the health vulnerabilities faced by undocumented and refugee immigrant children relate to compound risk factors that pervade their lives beyond health considerations, such as cultural and educational services, social networks, and legal status.

We expect the findings highlighted in this report to be useful to a wide range of audiences who are seeking to address this reality. We hope that everyday citizens, especially Utahns, are exposed to this report and understand the depth of immigrant disadvantage in their state and begin to embrace a commitment to address it. We further hope that any immigrant families who are exposed to this study are able to see what kinds of services are available to them in Utah today. While our study focuses on the state of Utah in the United States, we note that immigration is a global issue and our findings are likely to resonate with health service providers around the world.

In the ongoing discussion designed to break the cycle of vulnerabilities faced by immigrant families, it is vital to recall that different solutions are required for undocumented immigrant families than are required for refugee families. While many of the needs and vulnerabilities of these populations are similar, the “fear/familiarity dichotomy” requires agencies, in many cases, to approach the same problems in different ways depending on which demographic they serve. The provision of social and health-related services to newly arrived immigrants is a growing sector that has many lessons to learn, but it will become only more important as world conflicts continue to direct disadvantaged families to advantaged countries. Raising the level of cultural literacy related to navigating complex services and bureaucratic systems will be essential to breaking the cycle of vulnerability [8], and the participants in this study framed specific and tangible ways to improve the health of immigrant children and their families. Above all else, we hope that this study adds to the ongoing conversation between health-related professionals who are providing medical services to immigrant children across the world, the United States, and especially in Utah. It is through the steady accumulation of knowledge, research, experience, and collaboration that organizations like these will truly be empowered to, once and for all, fully and effectively break the cycle.

ACKNOWLEDGMENTS

The authors would like to thank the research participants, Dr. Christy Glass, Dr. Shannon Browne, and student Tori Valora for supporting this project in various ways.

APPENDIX A

Social Service Interviews

We prefer to make an *audio recording* of our interviews, whenever possible, to guarantee that we represent your comments correctly. We have every intention of *maintaining your confidentiality*. May we make an audio recording of this interview to ensure the accuracy of our report?

Thank you for participating in our study! Your opinion and expertise is very important to our project. Our focus is on immigrant children and their health and medical vulnerabilities.

We realize that there are different categories of immigrants –

- There are refugees who are fleeing conflict or persecution and are protected by international law.
- Then there are migrants who move for various reasons.
- Within the migrant population, there are also undocumented or unauthorized migrants who lack legal documentation or status.

It would be very helpful if you could speak to the differences in these groups as it pertains to your organization and your answers.

I expect this interview to last approximately 20-30 minutes. *You may choose not to answer any of our questions or ask that we conclude the interview at any time.*

Do you have any logistical questions for me before we begin?

1) Information about you/your organization

- A. Can you please state your name and the organization with which you work? (probe for details)
- B. How long have you been working with this organization?
- C. What is your current role and responsibilities with this organization?
- D. What kinds of healthcare-related services does your organization provide for children of immigrant families (age 0-18)?
- E. Does your organization target a specific population of immigrant families? (Probing: A particular type of immigrant as we discussed above? A certain region? A certain age? A certain gender?)

2) Now we'd like to ask you about HEALTH ISSUES of Children of Immigrant Families

- A. In your opinion, what are the most common medical or health *issues* experienced by the children of immigrant families that your organization serves?
- B. Are there any significant differences between immigrant boys' health-related needs and immigrant girls' health-related needs? (age 0-18)

- C. Are there any significant differences between the health-related needs of *refugee children, undocumented immigrant children, other immigrant children, and non-immigrant children*?
- D. One of the things we are interested in on this project is *environmental health* – health issues related to factors that are external to a person – such as air, water or soil conditions or in the built environment like houses, schools, or other places, or due to contaminants (like lead) or other exposures.

In your opinion, what are the most common *environmental* health issues experienced by the immigrant children that your organization serves? [Probing: pre-existing vulnerabilities? Or did they arise upon arrival?]

3) Next we'd like to ask you about HEALTHCARE ACCESS for Children of Immigrant Families

- A. Do children of immigrant families need to meet any *eligibility* requirements in order to access your organization's services?
- B. (if not addressed above) Are there any significant differences between the health-related *access* of the children of *refugee* families and the access of children of *undocumented immigrant* families?
- C. Are there any significant differences between boys' *access* to health care and girls' *access* to health care?
- D. What barriers do immigrants face in trying to access healthcare services?
- E. What barriers do organizations like yours face in attempting to provide healthcare related services to the children of immigrant families in Utah?

4) Finally, we'd like to ask your thoughts about reducing vulnerabilities faced by children of immigrant families in Utah

While our project is designed to identify these vulnerabilities, we are also very interested in identifying strategies to overcome them. [If appropriate, acknowledge successes mentioned above here.]

- A. What successes has your organization had in addressing the vulnerabilities faced by children of immigrant families in Utah?
- B. What actions do you believe could be taken by organizations – yours or others – to more successfully address these vulnerabilities?
- C. Are there any governmental actions you see as needed to address these issues?

Final Questions

- A. Is there anything we haven't asked or anything else that you would like to tell us about your experience in providing healthcare services to immigrant children?

- B. We would like to speak with representatives from as many social services as possible that provide healthcare services to immigrants. Can you think of anyone that is also familiar with the medical vulnerabilities faced by children of immigrant families with whom we should speak?

If so:

Do you know this person's email address? Phone number? Is this person affiliated with an organization like yours? What is that organization? Would it be okay for us to identify you as the source of the contact information? (It's not vital that we do so, but it's helpful). [if this gets complicated – suggest follow up email]

- C. Would it be okay if we email you with any additional questions that we might have?
- D. [Ensure we have email contact info] We will be sure to send you a report of our findings when we have it in mid-summer.

Thank you so much for your time!

Chapter 21

PARENTS' AND TEACHERS' BELIEFS ABOUT SCHOOL READINESS: WORKING TOWARD DEVELOPING MORE CULTURALLY RELEVANT INTERVENTIONS

Ellen Litkowski, MS and Ann Cale Kruger*, PhD

Department of Educational Psychology,
Special Education and Communication Disorders, Georgia State University,
Atlanta, Georgia, USA

ABSTRACT

The persistent disparity on educational measures between students from different socioeconomic backgrounds is often referred to as the achievement gap. To mitigate this achievement gap, many prior interventions have been designed to promote children's linguistic skills and overall school readiness. These interventions are often built upon majority-culture standards and traditions, despite the differing values and practices of many diverse communities. To more effectively support language and academic outcomes of children growing up in low-income households, we need to ground our interventions in the cultural values of specific communities, and better understand how parents and teachers are preparing children for their early academic careers. To further this understanding, the current work used focus groups with parents and teachers of preschool and Pre-K students. Focus group discussions revolved around two primary questions: 1) how do you conceptualize school readiness for your children and 2) what are the current oral language practices in the home and classroom? Differences in school readiness beliefs and practices were present across all three groups. Parents and teachers emphasized different school readiness skills. Additionally, mismatch between parents' and teachers' beliefs about students' learning may result in tension between the home and classroom environments. Future interventions might promote stronger communication between these two groups – allowing for a shift in perspective about the value of specific developmental and educational activities.

INTRODUCTION

Poverty is pervasive across the United States. It affects both adults and children, but has especially significant ramifications for children who are exposed from a young age – specifically from birth to the preschool years [1]. The poverty rate for United States (U.S.) children has been increasing since 2000. Approximately 22% of Americans under the age of 18 grow up in poverty [2]. High concentrations of wealth have exacerbated growing income disparity across the country. Such disparity results in inequalities in access to quality healthcare, housing and education.

Young children growing up in low-income and impoverished homes experience challenges in both developmental and academic realms [3]. Prior work demonstrates that children from low-socioeconomic households face poorer outcomes in both verbal and math achievement, as well as on more basic cognitive tasks [4]. Children growing up in poverty may also demonstrate more emotional, social, and behavioral problems, due in part to their increased exposure to stress [5].

Two significant influences on young children's future academic success are their language facility and their overall school readiness, which includes elements such as social-emotional competency, attention, and motivation. To better support children growing up in low-income households, many interventions have been designed to bolster these foundational abilities. As verbal ability supports success in other academic domains, language and reading interventions are particularly prevalent for these children. These interventions, however, often neglect to account for cultural differences across communities. Views and practices of specific communities influence how language and school readiness are fostered and what elements and skills are preference. Effectively supporting children's language and school readiness necessitates understanding their ecological influences by learning about individual community's beliefs and practices. Incorporating culturally relevant practices would strengthen the effectiveness of existing interventions. Understanding a community's cultural values and beliefs is understood to be of utmost importance in public health communication [6], and should be included in early childhood educational interventions as well.

Within the community, children's early caregivers (e.g., teachers and parents) play a significant role. The supportiveness of the home and classroom environment can strengthen or impede children's healthy development. The views of both parents and teachers are thus vital to creating a clear and thorough understanding of the child's cultural context. The current study used focus groups to learn about the views of parents and teachers regarding young children's language and school readiness to inform more culturally relevant interventions.

The Importance of Children's Early Language Environments

Prior work has shown that culture influences the role and purpose of language, particularly in regard to how adults expect their children to learn and use language [7]. Children absorb the language spoken around them. Adults – particularly the children's primary caregivers – thus play an important role in what and how a child learns language. The quantity and quality of a caregiver's speech affects components of language ranging from vocabulary size to language processing efficiency [8]. Hearing greater quantities of speech typically improves children's vocabulary size and diversity, as well as increases the length of spoken sentences. Children whose caregivers speak more also tend to develop greater speech processing efficiency [9]. These individual differences in language among children – specifically regarding lexical quantity and sophistication – can be seen as early as one year of age, highlighting the importance of promoting language within the early caregiving environment [10]. In addition to the grammatical and functional elements of language that children learn via adults, they also absorb the social functioning of language [11]. Language allows children to understand their role in the community, as well as what is expected of them as they age. This strong social component reinforces the impact that the community's beliefs and views have on their children's language development.

Research investigating the specifics of children's language outcomes based on differing language input has produced mixed results. This may in part be due to different measures of home language. While some studies define home speech as the entirety of language spoken in the home, others focus more on child-directed speech [12]. When in the home, parents may differ in the quantity of speech directed to other adults as compared to the quantity of speech directed to their child. Some researchers contend that this child-directed speech is even more critical than the overall spoken language [13, 14]. Child-directed speech, however, can serve multiple purposes. Parents can use directive speech – speech that is instructing children in some manner – or can use more elaborative speech, which serves to bolster conversation through back-and-forth communication. Differences in these types of speech can be seen among parents of different SES levels as well as among different ethnicities [13, 15]. For instance, among lower-income African American families, conversations are more likely to involve commands and directives, where children are expected to argue their positions when conversing with adults [11]. These elements may not prepare children for success in the mainstream education system, where more referential and elaborate language and more formal grammar are used.

In addition to the language spoken in the home, parents' literacy practices – both formal and informal – impact their children's language development. In general, formal literacy activities refer to those that focus specifically on the code, or print, whereas informal activities often involve exposure to print material, but concentrate on meaningful components such as story content or question-asking [16]. Joint activities such as shared book reading increase emergent literacy skills such as phonological and print knowledge, as well as more conceptual knowledge. Acquisition of such skills may take place at different times during storybook reading [17], but all are critical components to a child's later ability to read and comprehend. Parents may view certain language and literacy practices as ways to support their children's success in school. For this reason, the current work aimed to better understand parents' home language practices by eliciting conversations about school readiness.

Early School Readiness

Children's early success in school is not solely dependent upon their language abilities. School readiness encompasses a variety of skills ranging from academic to social-emotional to physical development. School readiness is particularly critical as children move from preschool to kindergarten. Children who meet the relevant school readiness goals demonstrate a greater likelihood of later success in school, both socially and academically [18]. At a young age, children are transitioning from spending the majority of their time in the home with their immediate family members to the classroom where they participate in structured interactions with peers and teachers. As children make this transition from primarily family interactions to peer/teachers' interactions, they are learning expectations and standards from both parents and teachers. Due in part to the differences between the home and classroom environments, parents and teachers may emphasize different skills – and consequently prioritize specific goals in a different manner. The current study led separate focus groups with parents and teachers in order to allow for an accurate representation of each group's beliefs to emerge.

Prior research has emphasized distinct differences between parents' and teachers' views on school readiness. In general, parents emphasize the importance of formal academic skills over social and behavioral skills [19]. Other studies have revealed that parents' views on school readiness are often related to their education level and socioeconomic status. Parents living in low-income areas felt that skills such as knowing phone numbers, how to count, and letters of the alphabet, were the most important readiness skills [20]. In an urban school district in New York, there was a greater home emphasis on compliance with authority and basic knowledge, such as knowing body parts, colors, and the alphabet [21]. Teachers' conceptions of readiness tend to include a range of social, emotional and cognitive skills. For instance, a study of kindergarten teachers tended to view preparing children for satisfying the social demands of schooling as of higher priority than academic skill development [22]. In regards to these social expectations, teachers typically refer to whether a child can verbalize their needs and desires, take turns with other students, and follow classroom directions. Teachers' expectations for students entering kindergarten also influence their judgments of children's problems and direct their attention to specific areas [23].

While research regarding parents' and teachers' conceptions of school readiness was robust over a decade ago, few recent studies have continued to examine these differences. This is in spite of the fact that readiness standards have changed dramatically over the past decade, and thus academic and developmental expectations for children may be quite different. To best prepare children for later success, it is important to understand the emphases of parents and teachers on school readiness components. More specifically, it is important to understand the emphases of parents and teachers within culturally, economically, and ethnically diverse settings. Both school readiness and language usage have been conceptualized as culturally dependent constructs [6]. The future societal roles caregivers envision for their child may influence what elements of school readiness they deem most important. As such, uncovering a specific community's beliefs about school readiness is vital to the development of future academic interventions.

The Current Study

Many prior interventions designed to promote children's linguistic, social, and academic development are grounded in middle class, majority practices, despite the differing values and practices of many diverse communities. To more effectively support developmental outcomes of children growing up in low-income households, we need to ground our interventions in the cultural values of the community, and better understand how parents and teachers are preparing their children for their early academic careers. We can understand the cycle of environmental health disparities as being perpetuated in part by cultural practices, but in order to determine how we can most effectively break this cycle – specifically in regards to education and language/literacy and communication (Figure 1), we need to understand what those cultural practices are. The goal of this work was to understand how parents and teachers of preschool and pre-K students, specifically those growing up in low-income households, conceptualize “school readiness,” how they subsequently help their children prepare for success in school, as well as what types of oral language practices are occurring in the home and classroom. The current study used focus groups to uncover the views and beliefs of parents and teachers. The two guiding research questions underlying the discussions within the focus groups were: (1) How do parents and teachers conceptualize school readiness? (2) What are the characteristics of oral language practices in the home and in the classroom?

Note: Arrows indicate where the current project intervenes to break the cycle of environmental health disparities.

Figure 1. Breaking the cycle of environmental health disparities.

METHODS

Research was conducted at one early childcare center in a large metropolitan city. The center provides services for children age birth through five and has multiple preschool and pre-K classrooms. The center is part of a larger organization that serves children growing up in low-income households. Teachers and parents of both preschool and pre-K children were invited to participate in this research. Recruitment occurred via flyers posted in the center as well as announcements sent to parents and teachers from center administrators.

Focus groups for teachers and parents were conducted separately. Three focus groups were held. One focus group was for preschool and pre-K teachers, one focus group was for parents of preschool students, and one focus group was for parents of pre-K students. One or two graduate research assistants led all focus groups.

Twenty-three African American men and women participated in the three focus groups. Three participants were male and 20 were female. Eight preschool parents participated, four pre-K parents participated, and eleven preschool and pre-K teachers participated. Prior to beginning the focus groups, participants were given consent forms to sign. After consent was acquired, all focus groups were audio-recorded. Focus group participants' comments directed the conversations, but research assistants provided guidance via additional questions as needed. Sample focus group prompts are included in Table 1. The duration of each focus group varied from one to one and a half hours.

Table 1. Sample focus group prompts

Research Question 1: How do parents and teachers conceptualize school readiness?	What do you do to help your child (student) succeed in school?
	What skills do you think are most important for your child (student) to succeed in school?
	What are some things you tell your child (student) about being a good student?
	What are the important things you think your child (student) should know at this age?
Research Question 2: What are the characteristics of oral language practices in the home and in the classroom?	How often do you have long talks with your child (student)? What kinds of things do you talk about?
	Do you make up stories to tell to your child (student), if so, what kinds of stories are these?
	What types of questions do you ask your child (student)? How often do you do this?
	What type of books do you and your child (student) like to look at? How often do you all read together?

Data Analysis

A trained graduate research assistant transcribed all focus groups. Focus group transcripts were analyzed using the thematic analysis framework developed by Braun and Clarke [24]. Thematic analysis follows six primary stages: 1) familiarizing yourself with the data, 2) generating initial codes, 3) searching for themes, 4) reviewing themes, 5) defining and naming themes, and 6) producing the report. Themes are intended to capture elements relevant to the research questions that emerge consistently throughout the data set.

A key step within thematic analysis is determining how to qualify or quantify the 'prevalence' of themes. One method for doing so is taking an exact count of conversational elements that are present. A potential weakness within this technique, however, is that the most prevalent conversational elements may not answer the research questions. Elements mentioned less often might provide more direct insight into those questions. For this reason, rather than relying on exact counts, the current research specifically examined conversational components that captured an important element related to the research question. Exact counts of themes are thus not included within the results.

RESULTS

Conversations from the focus groups revealed four primary themes. Two themes revolved around differences in beliefs or practices between the groups of participants, one theme depicted the language practices that parents and teachers felt were important for children's school readiness, and one theme emphasized group similarities.

Differences in Beliefs between Parents and Teachers

In both the pre-K parent focus group and the teacher focus group, elements of miscommunication between teachers and parents and misalignment between their beliefs regarding school readiness arose. For instance, teachers emphasized informal opportunities for teaching and learning, whereas parents – specifically pre-K parents – felt that their children's primary learning took place in formal, structured activities. The majority of Pre-K parents felt that skills such as knowing how to write your name properly, or being able to trace letters and numbers, were vital to their success in school. Supporting these skills required parents to sit with their child one-on-one, guiding them through their practices. One parent mentioned how these home experiences were different from what her children received in the classroom. She said, "They just letting you have circle time all day, and you just getting the learning when I'm home with you at the table." Parents of pre-K children also discussed the influence that technology had on their children's learning. Many parents referenced using educational programs, videos or applications as learning supplements for their children. Pre-K parents mentioned wanting more communication with teachers to guide their practices, and there was a sense of bitterness when one parent said "...But I haven't had a report from the teachers, so I'm not even really sure they're still doing it."

In contrast to the formal activities emphasized by pre-K parents, both preschool and pre-K teachers believed that children's learning experiences were richest in moments of play and exploration. Teachers viewed these activities as more developmentally appropriate than the formal learning activities they believed parents preferred. Moreover, teachers believed that parents thought that the children's playing was "just playing" – rather than "developing skills while they're playing."

The misalignment between parents' and teachers' views arose in the teacher conversation as well. Teachers appeared to sense parents' emphasis on formal education over informal education – referencing how parents gave them more respect when they led organized

activities rather than letting students have time for free play or exploration. One teacher stated, “Parents need to know what school is and what is developmentally appropriate for children.” Teachers also felt that parents expected them to do more behavioral management than teaching. There was substantial frustration due to the fact that they were viewed more as nannies than educators. Many teachers believed that parents used them to provide the discipline when they themselves didn’t want to; “They make you be the bad guy to do the parenting for them.” In general, teachers wanted parents to take more responsibility for their actions, teaching their children by example. Referring to a parent who didn’t follow the classroom hand-washing policies, one teacher said, “...it starts at home. It starts with the parent. You’re the child’s first teacher, your child sees you doing that, and then they’ll automatically do it too.”

Regarding differences in philosophies of education, one teacher mentioned that she had witnessed a generational gap in what constitutes education. This teacher discussed how this generational gap is seen in both parents and teachers. In teacher training sessions, the developmental emphasis within education had only recently arisen, and was influencing practices within the classroom. Just as teachers were exposed to multiple educational philosophies, groups of parents from different generations have had different academic experiences. Their academic experiences influence their perception of what type of education is most effective and how it should be structured. According to some teachers, parents expect the same type of education for their child that they themselves received. Understanding what educational activities are developmentally appropriate for their children is important not just for teachers, but for parents as well.

Differences in Beliefs between Preschool and Pre-K Parents

Two separate focus groups were held for parents of preschool students and parents of pre-K students. Themes discussed in each of these focus groups were strikingly different. Parents of preschool students emphasized the importance of supporting character traits such as independence, self-awareness, creativity, and responsibility. For them, these abstract qualities were vital to their child’s future success in school. One parent said, “I encourage him to be very independent, so that he feels that he can do anything. I allow him opportunities to [...] accomplish things. I try to encourage creativity because I feel that is something that in many ways lacks with our little ones.” To support this creativity and independence, many parents discussed strategies for extending conversation, “not ask[ing] yes or no type questions,” in order to support their child’s interest in specific areas. Several parents mentioned scenarios in which they could support their child’s interests, such as taking field trips, conducting science experiments within the home, and participating in music classes.

Parents’ desire to support their children in these more abstract and creative qualities was not present in the conversation with pre-K parents. Instead, the primary emphasis was behavioral compliance. All parents mentioned that having good behavior was the most important component of being a good pre-K student. One parent said, “Behavior is most important to me ‘cause they can’t learn anything if you’re acting loud and crazy.” Paying attention to authority figures and being respectful to them were key component of maintaining good behavior. References to listening to the teacher were common; “I tell my

kids to sit down and listen to the teacher. Don't over-talk your teacher. Listen to what she says, then respond." These behavior rules were especially important to those parents whose children were girls. Whereas parents felt that their male children listened to instructions, the girls were consistently referred to as "having a sassy mouth," "doing what they want to do," and "playing the parents against each other."

Parents' Beliefs about Oral Language Practices

One aim of the current study was to learn more about oral language practices within the home and classroom. Separating references to language practices from discussions of school readiness, however, was challenging. Parents talked about strategies to promote their children's language abilities, such as reading and writing practices, as they related to their child's success in school. Within the context of school readiness, a dichotomy between directive and elaborative language arose between pre-K and preschool parent discussions. As previously mentioned, directive speech is meant to instruct, whereas elaborative speech is meant to foster back-and-forth communication. Pre-K parents used more directive language strategies, discussing their use of formal teaching practices to support their children's verbal and writing ability. These parents mentioned components such as tracing letters, teaching their children to spell and write their names, and learning how to count to 100. Preschool parents, however, discussed using more elaborative techniques. These parents talked about using open-ended questions to promote language development, and capitalizing on their child's interests. As one parent said, her daily goal was to "try to dialogue with my son and do conversation."

Groups' Shared Investment in Supporting Their Children

An important component of all three focus groups was that both parents and teachers strive daily to support their children. While this support may not manifest itself in the same manner among the different stakeholders, the entire community's desire to provide a better future for their children was evident in all conversations. When asked what the best thing about being a parent was, parents responded with statements such as, "We build and we grow and we learn together," "Being a great example to your child," and "We have these two little people who love us unconditionally." Teachers shared this same enthusiasm for supporting their children, saying, "You know, family has support here, but my stake is for the children."

DISCUSSION

Overall, parents and teachers talked more about general school readiness concerns, rather than focusing solely on language. Both groups did mention certain language practices, but these comments were primarily embedded within readiness goals. This shift may reflect broader policy changes affecting early childcare centers' learning standards and frameworks.

These frameworks have begun to focus on more than just reading and math, to include social, emotional, and cognitive aims as well.

The current work confirmed prior research findings regarding parents' and teachers' beliefs about school readiness [20-22]. Definitions of school readiness are common, but these definitions vary among different groups of individuals. Among parents and teachers, school readiness goals ranged from abstract qualities such as independence and self-esteem, to learning numbers and letters, to knowing how to behave appropriately. Even after the components are delineated, beliefs regarding their relative importance differ. In the current work, there were philosophical differences regarding the purpose, practices, and theories of early childhood education between parents and teachers. Perhaps more importantly it appeared that these differences in beliefs about education practices negatively impacted the relationship between parents and teachers. The misalignment between parents and teachers resulted in tension – despite both groups having the same goal of best supporting the development of their children.

One limitation of the current work is related to recruitment issues. Parents who elected to participate in the focus groups may not provide an accurate representation of the beliefs and practices of all parents within the childcare center. Teachers who referenced struggles with parents may be referring to less involved parents, likely those who did not participate in a focus group. Future work should attempt to recruit a wider sample in order to gain a more holistic view of the beliefs and practices of specific communities. Obtaining a larger sample, specifically one including parents of varied levels of involvement, would promote greater generalizability to other populations. An additional limitation of the study was related to the two research questions. The study aimed to better understand parents' home language practices as well as their beliefs regarding school readiness. Separating discussions of language from discussions of school readiness was challenging, perhaps because parents had already been primed with the first question to discuss school readiness. Future studies using focus groups should develop more nuanced questions in order to understand language as separate from formal readiness practices.

Findings from the current work have wide-ranging policy implications, specifically for parent and teacher development. Understanding the views of key stakeholders, such as parents, teachers, and community leaders, provides a method to encourage bottom-up policy development. Head Start, the largest federally funded childcare provider, considers parent-teacher communications to be of utmost importance to children's early learning. Head Start emphasizes that parents are true partners in their children's development and education. Activities such as parent-teacher conferences, and individual goal-setting within those conferences, make up a central portion of parent-teacher communication. Some programs, however, have experienced lower levels of parent involvement than desired. While beneficial, communication strategies may suffer if parents' and teachers' beliefs about basic school readiness are not aligned. Knowing how each set of caregivers views children's school readiness may promote more productive conversations within teacher-parent conferences. Future interventions need to capitalize on the shared investment of parents and teachers in the lives of the children they support. Enhancing parent and teacher collaborations may require more opportunities for interaction, in safe spaces outside of conferences. If parents are to believe that they are truly partners in their child's education and development, then their beliefs must be heard and validated more by teachers. Conversely, teachers need to share their views about what classroom activities are most developmentally appropriate for their

children. The results from this work emphasize this need - indicating that common educational and developmental goals and standards for children need to be established. For a community to best support their children, interventions must be grounded in their beliefs – but their beliefs must first be better aligned.

ACKNOWLEDGMENTS

This research could not have been completed without the help of Dr. Nicole Patton-Terry, Dr. Gary Bingham, Dr. Maggie Renken, Johari Harris, and the staff, parents, and teachers of the early childcare center. Additionally, the support of the Break the Cycle members was vital to the development and completion of the project.

Chapter 22

“I WAS SCARED OVER THERE.” FAMILY WELL-BEING AFTER RELOCATION FROM A DISTRESSED PUBLIC HOUSING DEVELOPMENT

***Kirstin Frescoln*, CPM, Mai Thi Nguyen, PhD,
William Rohe, PhD and Michael Webb, PhD***

Department of City and Regional Planning,
University of North Carolina at Chapel Hill,
Chapel Hill, North Carolina, USA

ABSTRACT

This study examines changes in well-being among families relocated from the Boulevard Homes public housing development in Charlotte, North Carolina. Prior to demolition, Boulevard Homes had high rates of violence, drug use, and teen pregnancy relative to other neighborhoods in the city. Households were relocated to another public housing development or to private-market housing with a voucher and were provided case management services for up to five years. Fifty-five percent of those living in Boulevard Homes were children under the age of 19 years. Methodology: This study utilizes mixed-methods and a socio-ecological approach to understanding the context of adverse childhood experiences, while living in a distressed public housing development. We asked how well-being was affected five years after relocation. Quantitative methods examine which variables of interest were most affected by the move and associated with an improvement in overall quality of life. Semi-structured interviews conducted in 2015 contextualize the quantitative findings. Results: Both the quantitative and qualitative data indicate that relocation resulted in significant improvements in perceptions of safety amongst those individuals who stated their life was “much better” than when they lived in Boulevard Homes. Parents cited safety and well-being concerns for their children when discussing the positive outcomes of the move. Discussion: Results confirm previous housing mobility studies – providing quality housing in safe neighborhoods improves well-being. To break the cycle of adverse childhood experiences and poverty leading to

health disparities, communities must seek to improve living conditions of vulnerable populations while providing services to increase economic mobility.

Keywords: public health, public housing, well-being, adverse childhood experiences, toxic stress, health disparities

INTRODUCTION

Adverse childhood experiences (ACE) such as abuse, neglect, household dysfunction, and exposure to violence have been linked to poor behavioral decision-making and increased incidence of mental health diagnoses and chronic health conditions [1]. Adverse experiences during childhood, which continue over a long period of time as opposed to single events or brief periods, may result in the development of toxic stress [1]. Toxic stress occurs when the body's stress response system is activated over a long period of time. Children exposed to extreme poverty or hunger, repeated acts of violence, and abuse or neglect as a result of parental substance abuse and maternal depression experience chronic insecurity and fear resulting in toxic stress [1]. The physiological responses to toxic stress causes the body to biologically embed these early adverse experiences and triggers the neuroendocrine, autonomic, metabolic, and immune systems to malfunction leading to an increased risk of early mortality [1].

While not specifically intended to address ACE or toxic stress, the Department of Housing and Urban Development's HOPE VI program delivered interventions that addressed both concerns. From 1993–2010, HOPE VI provided funding to local housing authorities to redevelop highly distressed public housing developments [2]. During redevelopment, households could opt to relocate to another public housing development or to private-market housing with a Housing Choice Voucher (HCV) also known as Section 8. Many households – especially those relocating with a voucher – moved to higher-quality and safer neighborhoods, resulting in a reduction of ACE and improvements to health and well-being [3].

This paper explores how HOPE VI affects individual and family well-being when mothers with dependent children relocate from a highly distressed public housing development to better quality living environments. It adapts Shonkoff's framework of health disparities [4] to examine how the environment in which families live contributes to maternal health and well-being and how these, in turn, affect children's current and future well-being. We hypothesize that:

- Parents who report greater safety and neighborhood satisfaction post-relocation will report improved measures of well-being.
- Children will benefit from the move to better neighborhoods due to reductions in exposure to harmful environmental factors, increases in healthful factors, and improvements to maternal health and well-being.

We find that moving families away from a community marked by violent crime to new neighborhoods where families feel safer from violence and property crime had a significant impact on feelings of well-being.

In this paper, we explore how the socio-ecological environment in which individuals live affects their health and well-being either through increased exposure to stressors and risk, or protections from these potential harms. We then examine how housing mobility interventions may serve to remove households from many of the environmental risks associated with reductions in health and well-being. Finally, we discuss how HOPE VI, which combines mobility and support services interventions, seeks to address the socio-ecological environments of highly vulnerable public housing residents by moving the household from distressed public housing developments to better living conditions while providing up to five years of community support services to improve household economic mobility. Our study of the Charlotte Boulevard Homes HOPE VI project is used to illustrate how HOPE VI aims to intervene in the cycle of environmental health disparities experienced by children and adults living in distressed public housing. Finally, we recommend how policy makers can intervene in the cycle of health disparities and improve overall well-being by providing services to address the social determinants of health.

Neighborhood Effects on Well-Being

We begin with a brief introduction to well-being. Since the World Health Organization (WHO) declared in 1946 that "health is not the mere absence of diseases but a state of well-being" [5], researchers, physicians, policy makers, and others have sought to define and measure the concept [6]. Well-being is complex; it encompasses the quality of individual health and relationships as well as an individual's sense of security and agency. These are, in turn, intrinsically linked to the individual's environment and access to resources. Well-being was defined by Shin and Johnson as "a global assessment of a person's quality of life according to his own chosen criteria" [6] and by the WHO [6] as,

People's perception of their position in life in the context of the culture and value systems in which they live, and in relation to their goals, expectations, standards, and concerns. It is a broad ranging concept affected in a complex way by the person's physical state, personal beliefs, social relations and their relationships to salient features of their environment

As a multidimensional concept, it takes into account many aspects of an individual's life that combine to produce an overall feeling of well-being [6]. Although well-being is sometimes established through application of a set of objective criteria such as income, chronic disease, and access to key resources such as housing, safe water, nutrition, and education, it can also be measured by asking the individual to rate his or her own sense of well-being or overall quality of life [7]. The individual considers the many dimensions – health, income, safety, happiness, and achievement – and determines whether these dimensions combine to produce either a global feeling of positive or negative affect [6].

Socio-ecological models explore how the ecology of the environment impacts the well-being of those living within the environment [7]. Our social ecology includes our immediate

family environment as well as the neighborhood in which we live, work, play, go to school, and meet friends. Children present a special case of social ecology as they have very little control over their environments. They live within families, families live in houses, and houses are located within neighborhoods. This “nested” aspect of social ecology means that to understand health and well-being, we must take into account not only the characteristics and biology of the individual, but also their family, home, and neighborhood environments. These linked environments are collectively referred to as the social determinants of health: the quality and quantity of access to resources as a result of education, of income and of where we live, work, and play [8].

In the United States, the resources provided through municipal services such as schools, police, and parks are largely funded by local tax revenues, particularly property taxes. As a result, neighborhoods with higher concentrations of low-income residents generally have lower-quality schools, strained public services, fewer parks, and a less robust business community [4]. Historical practices of legal segregation and on-going practices of social and economic segregation have produced many low-income neighborhoods with significant minority populations [5].

These low-income neighborhoods are also more likely to be burdened by extremely poor housing conditions and locally unwanted land uses (LULUs) such as high speed roads and pollution sources such as transportation depots. The social, economic, and physical factors of low-income neighborhoods also increase the incidence of crime and violence [4]. Environmental risks in the neighborhood and poor quality housing contribute to the development of chronic health conditions such as asthma, anxiety, and depression as well as acute injuries such as those related to unsafe traffic, poor housing conditions, and violence [4]. The physical, economic, and social conditions of these neighborhoods often isolates residents from environmental resources such as grocery stores and parks and from the social and economic resources of job and educational opportunities [7].

Poverty, violence, and isolation from opportunity contribute to stress, fear, and distrust within these communities making them less able to mobilize the benefits of social capital [7, 9]. Collective efficacy, one form of social capital, comes from the social cohesion born of a sense of shared experience and responsibility. Social cohesion empowers neighbors to address problems within their community. When neighbors are stressed and fearful, they are reluctant to become involved and invested in their communities [11]. Bridging social capital is another form of social capital which occurs when diverse groups of people share a wide range of knowledge, access to jobs, and other resources across informal networks. The information shared through these networks provides greater opportunities to improve household and neighborhood conditions than does more traditional bonding social capital which tends to occur between family and friends with similar sociodemographic characteristics [12]. Individuals who live in neighborhoods that lack diversity of economic and social resources are less likely to benefit from the information sharing resulting from bridging social capital, resulting in further isolation of the household [12].

Stress resulting from living in high-poverty neighborhoods with significant social disorder and insufficient resources may lead to depression and anxiety for many of the individuals living there [13, 14]. Residents in these neighborhoods are almost twice as likely to suffer from depression as residents living in higher-income neighborhoods, even after controlling for socioeconomic and health factors [15, 16]. The individual does not need to be directly affected by social disorder and crime to develop mental health disorders such as

anxiety and depression. Perception of social disorder and fear of future risk of becoming a victim also increase the odds of adult depression [17]. Neighborhood stressors and the lack of social supports contribute to the development of chronic mental health disorders [13, 14, 17].

Children in high-poverty areas are at even greater risk as a result of the reduced opportunities and greater exposure to negative experiences and of the negative effects these neighborhoods have on their caregivers [9]. High-poverty neighborhoods lack access to quality resources such as schools and parks, and children living in these neighborhoods are exposed to greater rates of social disorder and environmental hazards such as air, water, and noise pollution [4, 9]. These children are also more likely to grow up in female-headed households that lack financial, social, and emotional resources and security to protect them from these hazards [9, 11].

Children suffer as a result of familial poverty and maternal stress. Poor, single, mothers living in high-poverty neighborhoods are at higher risk for developing mental health disorders, particularly depression and anxiety [6–9, 12–14]. These mothers are less capable of effective parenting and more likely to neglect or abuse their children as a result of their mental health status or substance use [14, 15]. Maternal neglect and inconsistent parenting practices negatively affects children's health [20] and their educational outcomes [21]. These outcomes remain even after controlling for socioeconomic factors [6–10, 16]. Children living in high-poverty neighborhoods have a greater risk for increased harm not only because they are exposed to environmental and social hazards but also because their families do not have the financial and emotional resources to adequately protect them and mitigate the harm [12–15].

Toxic Stress: Its Timing and Impacts on Adult Outcomes

Stress is one of the body's mechanisms for protecting itself; the complex psychophysiological response serves to keep us safe in times of danger. Not all stress, however, is protective [1]. Stress can be managed and normalized when experienced within the context of safe and supportive relationships. Tolerable stress includes those experiences which could potentially alter brain structure due to increased and prolonged cortisol production but which are mitigated through experiences of safe and supportive relationships. Toxic stress occurs when an individual is exposed to prolonged, frequent, or particularly intense events which trigger the body's stress-response system in such a way that brain architecture and other body systems are significantly and permanently affected [1].

Thus, stressful experiences during childhood can produce debilitating life-long effects if not sufficiently mitigated by the care of supportive relationships. Extreme poverty, caretaker abuse or neglect, family or community violence, maternal depression, and parental substance abuse can trigger a heightened and prolonged stress-response resulting in cognitive impairment, chronic mental illness, and physical disease. These adverse childhood experiences (ACE) impact children differently from adults because of their specific developmental, psychological, and physiological vulnerabilities [16]. Exposures occurring at particularly susceptible periods can permanently alter the body's regulatory physiological processes. Adverse childhood experiences that contribute to toxic stress have been linked to increased risk of chronic heart and lung disease, cancer, anxiety and depression, and

behavioral risks such as substance abuse and addiction, teen pregnancy, obesity, smoking, and physical inactivity [1].

Children who grow up in poverty are at greater risk for ACE and toxic stress due to their disproportionate exposure to family chaos, environmental stressors, and traumatic experiences [1]. Residing in high-poverty neighborhoods increases children's risk for toxic stress because of their exposure to the ACE of extreme poverty and community violence and the likelihood that their mothers will suffer from depression and anxiety [16]. These mothers are less likely to be able to protect their children and more likely to neglect or abuse their children due to the environmental stressors experienced [1, 17–21]

Theory of Mobility on Individual and Family Outcomes

Recognizing the potential harm of concentrated poverty, some scholars and policy makers argue that households living in neighborhoods of concentrated poverty should be “deconcentrated” by moving them to economically and socially integrated neighborhoods [3, 10–12, 22]. These policies seek to address the enduring interconnectedness of race, poverty, and disadvantage which contribute to the social determinants of health [8, 11, 22]. Programs and policies that have sought to address concentrated poverty have included Gautreaux, Moving to Opportunity, HOPE VI, and the expansion of the housing choice voucher (HCV) program [3, 22, 23].

One of the first “tests” of deconcentration came as a result of a 1966 lawsuit brought by Chicago public housing residents and the NAACP against the Chicago Housing Authority. The suit alleged that the housing authority had violated the 5th Amendment and the 1964 Civil Rights Act by siting their public housing developments in neighborhoods that were majority African-American with high concentrations of poverty and social disorder. In 1976, a US Supreme Court decision, *Hills v. Gautreaux*, ordered the Chicago Housing Authority to provide HCVs to residents so they could move out of the disadvantaged neighborhoods [3]. Eligible households were given an HCV and assigned housing in neighborhoods that were less than 30% African-American.

After several years, those individuals living in suburban neighborhoods reported much better outcomes. These residents were more likely than their urban counterparts to be employed and off welfare, report better mental and physical health, and have completed educational programs (such as high school for children living in the household) [3]. The results provided some of the first evidence that deconcentration was an effective strategy to combat urban poverty, and provided support for a major policy and funding shift away from traditional public housing developments and toward increased funding for HCVs and mixed-income developments [23].

Moving to Opportunity (MTO) and HOPE VI

As part of this funding and policy shift, Congress and HUD also funded two new programs: the Moving to Opportunity (MTO) housing experiment and the HOPE VI housing redevelopment program. Amongst other goals, both 1993 initiatives sought to expand

understanding of the impact of deconcentration on the outcomes of households living in public housing [3].

MTO was an experiment designed to rigorously test the results of Gautreaux. It randomly assigned public housing households to one of three groups. A 'treatment' group received an HCV and relocation counseling that required the households to initially relocate into a neighborhood with less than a 10% poverty rate. A "comparison" group received an HCV without any location restrictions or counseling, and a "control" group remained in public housing. Families in all three groups were tracked between 1995 and 2005 [3].

To the disappointment of policy makers, findings from MTO did not match those of Gautreaux. Within the experimental group, adults reported little to no improvement in employment or income, children's educational outcomes did not improve, and there were even some increases in delinquency among young males [3]. Despite this, there was some cause for optimism. Women and girls experienced significant improvements in physical and mental health which were attributed to changes in the women's sense of safety. Adult women experienced reductions in obesity, and both women and girls reported reductions in depression and psychological distress comparable to effective psychotherapeutic treatments [3]. New research has found that although parents did not experience economic benefits from the move, their children, who were under age 13 at the time of the move, did benefit. These children were more likely than their comparison or control counterparts to attend college and attend better colleges (by 2.5 percentage points), had better annual incomes by roughly \$3,500 (31%), and more likely to marry (by 2 percentage points) [24]. Together, these findings suggest that mobility strategies may prove to be an effective intervention for the social determinants of health [3, 7, 8, 23].

HOPE VI was another policy experiment to improve housing conditions for and reduce the concentration of public housing residents in high-poverty neighborhoods. HOPE VI provided funding to: (i) help households in developments targeted for demolition move to either another public housing development or to private rental housing with the support of a HCV during redevelopment; (ii) provide community support services (CSS) to ease families' transitions from the original housing unit to their new communities and help them make economic gains, and (iii) redevelop the original site to new, mixed-income housing. The program envisioned that displaced residents, would return following redevelopment [25].

Like Gautreaux and MTO, one of the goals of HOPE VI was that families would experience gains in employment, education, income, and health once they were removed from their poor living environments. HOPE VI, however, sought to expand upon the mobility intervention by requiring housing authorities to provide community supportive services (CSS) to relocated residents in an effort to increase household economic mobility. These services assessed household needs and then helped connect residents to education and job training support as well as referrals for physical and mental health interventions and family counseling or other child-focused supports [3, 25].

HOPE VI has produced mixed results. It largely succeeded in demolishing distressed public housing developments, reducing crime, and improving property values in the surrounding neighborhoods [25]. It has not, however, significantly increased the economic mobility of residents or effectively returned former residents to the redeveloped sites [25]. Most did not return because they could not meet income and employment qualifications for the mixed-income site or because they did not want to move out of their HCV-funded rental apartments or homes [25].

HOPE VI as a Health Intervention

Despite these criticisms, HOPE VI has positively affected the well-being of many relocated residents [3, 25, 26]. Although not envisioned as a health intervention per se, many of the program’s elements address the origins of health disparities [4, 7, 8]. Two of HOPE VI’s major goals – improving affected residents’ housing and neighborhood conditions and enhancing their economic mobility – can be viewed as environmental health interventions to reduce health disparities [4, 7, 8].

Figure 1 displays the cycle of environmental health disparities. HOPE VI interrupts this cycle by relocating residents into higher-quality housing and neighborhoods. Further, CSS addresses educational, employment, and health barriers by connecting the residents to education, job training and placement, and health services [3, 25].

Although the quality of public housing is regulated [18], public housing developments targeted for redevelopment through HOPE VI were older and suffered from inadequate maintenance and upgrades. Plumbing, HVAC, and roofing tended to be at or beyond their intended lifespans resulting in leaks and mold and mildew within units. Construction codes, in place when the developments were built, have since been upgraded to reflect increased knowledge of building materials and potential hazards. Improved understanding of physical plan and building design has also resulted in newer public housing developments that increase defensible space and promote positive social engagement [20].

Adapted from Shonkoff’s biodevelopmental framework for understanding health disparities [4] and Break the Cycle of Environmental Health Disparities [28].

Figure 1. HOPE VI as an intervention into the cycle of health disparities.

While the physical conditions of public housing developments targeted for demolition under HOPE VI contributed to poor physical health, the social conditions of these developments contributed to poor mental health. HOPE VI housing developments tended to be located in highly segregated communities with little access to retail stores or employment opportunities. Drug trafficking and other crimes were common in these neighborhoods. Few adults were likely to have completed high school or be employed. Finally, early child bearing and single parenthood contributed to these conditions which tended to be intergenerational [27].

In addition to these stressors, in order to qualify for traditional public housing, household income must generally be 30% or less of the federal poverty level [23]. Public housing in the US is not an entitlement: therefore, local housing authorities establish "preferences" to help them prioritize households on the waiting list [23]. Preferences often include homelessness, domestic violence, or child neglect or abuse. Together, these socioeconomic factors make public housing residents highly vulnerable to health disparities [1, 8].

As a result of these vulnerabilities and exposures to adverse childhood experiences, most residents subject to HOPE VI relocation reported very poor overall health, high rates of chronic health conditions and mental health disorders, and body mass index (BMI) scores indicative of obesity. These health conditions are not only worse in comparison to the overall population but also worse than comparable cohorts, including those in poverty and racial minorities [26].

STUDY SITE

Understanding the significant socio-ecological risks that households are exposed to while living in highly distressed public housing, our study seeks to understand how the wellbeing of mothers with dependent children is affected by a move from Boulevard Homes in Charlotte, North Carolina. We employ data collected as part of a larger evaluation of the Charlotte Housing Authority's (CHA) HOPE VI Boulevard Homes redevelopment. Using the 2010 and 2015 surveys in conjunction with resident interviews we seek to better understand the stressors experienced while living at Boulevard Homes and how these stressors were affected by moving to new residences and neighborhoods.

Boulevard Homes was originally constructed in 1969 on a 34-acre site, 4.5 miles west of downtown Charlotte. The development comprised 300 housing units in 121 buildings. By 2007, the development had significant physical and social problems; CHA's application to HUD notes that "demolition of all structures on the site is justified based on the extreme physical obsolescence of the units, buildings, and systems" [23]. Much of the deterioration was attributed to site and building design flaws which contributed to the development of mold and mildew within the units. Poor grading also led to flooding. Homes were damaged by obsolete construction standards and materials life cycles that contributed to roof leaks, plumbing prone to recurring problems including bursting pipes, and inadequate cooling and heating. Asbestos was also detected in the flooring materials and joint compound used in construction. All of these factors suggest residents were exposed to significant levels of environmental toxins prior to relocation. Access to the site and layout of the buildings also

contributed to physical isolation from the rest of the city and creation of “indefensible” spaces that fostered criminal activity and a sense of insecurity among residents [23].

Boulevard Homes was considered a “crime hot spot” defined as a location where there were five or more overlapping monthly incidences of crime. Incidences of violent crime (homicide, rape, robbery, and aggravated assault) were five times greater than the city average, juvenile crime was 2.8 times greater than the city average, and property crime was twice that of the city average [23].

METHODS

Quantitative data for this study are drawn from two surveys completed by Boulevard residents: one prior to relocation and a second five years after relocation. These surveys had response rates of 76% (223 of 291) and 52% (108 of 204) respectively. The sample is restricted to households that completed both surveys and included at least one child under the age of 19 at the time of the 2010 survey prior to relocation. This results in a survey sample of 44 households.

Qualitative data are drawn from the open-ended survey questions and from interviews with a randomly selected group of former Boulevard residents still living in CHA housing five years after relocation. While 20 heads of household were interviewed for the larger study, only 13 had a child under the age of 19. All interviews were recorded and transcribed.

Analysis

We were interested in learning how quality of life or well-being was affected by the move. We analyzed quantitative data using paired T-tests and Chi Square as determined by the data’s structure to measure for significant differences in the 2010 and 2015 variables associated with health and well-being and an individual’s likelihood to rate their overall well-being in 2015 as “much better” than when they lived in Boulevard Homes. Heads of household were asked, “Comparing your household’s overall quality of life, to that of Boulevard Homes, would you say your household’s current overall quality of life is: much better, somewhat better, about the same, somewhat worse, or much worse?”

Variables tested include perceptions of individual health, housing, and neighborhood (see Table 1). Health questions included overall health, number of chronic conditions, depression, anxiety, and a measure of food (in)security. Housing and neighborhood questions included perception of crime, perception of safety, opinion of current home, opinion of current neighborhood, and an index measure of social capital. Other variables of interest include age of the head of household and educational attainment, the household income as reported in June 2010 and June 2015, and the number of children age 17 years or under living in the home in December 2015.

Prior to analysis, we explored the presence and patterns of missing data that were found to be moderate and appropriate for imputation. Multiple imputations using Stata were conducted to create complete data sets. Standard statistical tests confirmed that the data were normally distributed within acceptable limits and did not require adjustment.

Table 1. Variable of interest

Variable	Survey Question	Type	Measure
Self-rated Health	In general would you say your health is...	Ordinal	1= Excellent - 5= Poor
No. Chronic Health Conditions	Asthma, Hypertension, Type2 Diabetes	Continuous	Sum 0-3
BMI	Calculated by reported weight and height	Continuous	Obese = >30
Accomplish Less Due to Anxiety	During the past four weeks, how often did y	Ordinal	0= None - 4=All of time
Work Less Carefully Due to Anxiety	During the past four weeks, how often did y	Ordinal	0= None - 4=All of time
CES-D Score	10 questions used to screen for depression	Continuous	Possible depression = >10
Age of Head of Household	Calculated by birthdate	Continuous	
Number of Children	Housing authority administrative records	Continuous	
Income in Thousands	Housing authority administrative records	Continuous	
Ran Out of Food	How often during past 12 months did you run out of food before you got money to buy more?	0/1	Sometimes or Often = 1
Sense of Safety	How safe would you feel being out alone in the parking lots, the lawns, the street, or sidewalks right outside your home at night?	Ordinal	4=Very Safe - 1=Very Unsafe
Social Capital	Do you know any neighbors who... have a car you could borrow, would babysit your children, are good at using a computer, are active in a community organization, would bring you medicine or food if you were ill, you can discuss personal matters with, would lend you a \$100"	Continuous	Sum yes/no responses, household assigned a score reflecting deviation above or below median
Months Active in Case Management	Housing authority administrative records	Continuous	0 - 57
Better House	Comparing your current housing situation to that of Boulevard Homes, would you say your current housing situation is...	Ordinal	5=Much Better - 1=Much Worse
Better Neighborhood	Comparing your current neighborhood to that of Boulevard Homes, would you say your current neighborhood is...	Ordinal	5=Much Better - 1=Much Worse
Overall Quality of Life	of life to that of Boulevard Homes, would you say your household's current overall quality of life is...	Ordinal	5=Much Better - 1=Much Worse

As mentioned above, qualitative data are drawn from two sources: open ended survey questions and semi-structured interviews with heads of household. The two open-ended survey questions were "What have been some of the best things about relocation from Boulevard Homes?" and "What have been some of the worst things about relocation from Boulevard Homes?" The semi-structured interviews asked about a wide range of experiences related to the move from Boulevard Homes including: finding and settling into a new home and neighborhood, children's adjustments to the new community and new school (if applicable), the health of the head of household and household members, employment and educational experiences, perspectives on the helpfulness of the CSS case management experience, aspirations for the future, and family interest in, or barriers to, moving back to the redeveloped site.

Qualitative data were uploaded into the data analysis program Atlas.ti and analyzed using deductive and inductive coding. Deductive codes included those based on the variables of interest such as health, safety, well-being, children, and violence. Inductive codes were also generated and applied as they emerged from the data. These included subjects related to fear, independence, and self-worth. Once coded, frequencies and co-occurrences were compared to findings from the quantitative data seeking themes of convergence or divergence across the two data sources.

RESULTS

The residents living in Boulevard Homes experienced a number of markers of social distress, particularly in comparison to other Charlotte area residents (see Table 2) [23]. In 2010, Boulevard residents had a median household income of \$8,088, 92.8% of households received food stamps, and only 20.4% of residents indicated employment as a source of income. In comparison, Charlotte residents reported a median household income of \$52,148 and only 13.1% received food stamps. Only 51% of the heads of household in Boulevard Homes have a high school diploma or GED. Youth living in Boulevard also struggled to complete high school — 14.3% were high school dropouts as compared to 5.1% — and reported very high rates of teen pregnancy — 21.6% as compared to 6.4% of Charlotte residents [23]. At the time of the move, there were 286 households with a total population of 828, 55% of whom were children; 152 were ages 0-5 (18%), 199 were ages 6-12 (24%), and 108 were ages 13-17 (13%) [23].

Tables 3 and 4 provide a summary of the quantitative variables. The age range for the head of household spans from 27 to 86 years and is indicative of grandparents either cohabitating with adult children and grandchildren or assuming parenting responsibility for their grandchildren. On average, Boulevard heads of household dropped out of high school sometime before reaching the 11th grade. Household income shows a broad range from zero to roughly \$36,000. When one high-income outlier is removed from the average, the new mean income is \$10,860.

Table 2. Boulevard Homes Compared to Charlotte Residents

	Boulevard Homes	Charlotte
Household Income	\$8,088	\$52,148
Food Stamps	93%	13%
High School Dropout	14%	5%
Teen Pregnancy	22%	6%

Overall Quality of Life	44	4.20	1.07	1	5

Boulevard Homes had an unusually high number of children because it was one of the few developments with four and five bedroom units. Households that included children had between two and three children on average, but several households had between six and eight children. The average age of the children at the time of the relocation was just under nine years old. Households were given a choice of moving to another public housing unit or to move using an HCV, and 64% of all relocatees moved using an HCV. Almost all (91% or 40 of 44) households in our sample moved to a privately owned apartment or house with the assistance of an HCV. The percentage of HCV movers is higher in our sample because it is restricted to families with children, many of whom were anxious to trade public housing for their own home with a yard.

We began the analysis by conducting significance tests to understand which conditions in both 2010 and 2015 had a statistically significant effect (at the 0.05 level or above) on the household's overall quality of life in 2015. As seen in Table 5, those households that experienced lower levels of safety in 2010 while living in Boulevard Homes reported a much better quality of life after relocation.

Table 6 reviews the same variables of interest but also contains several variables that asked households to compare their current living situations to Boulevard Homes. Households that moved using a housing choice voucher, had higher household incomes, and reported that their homes and neighborhoods were better than when they lived in Boulevard Homes also reported higher overall quality of life in 2015. None of these results are surprising given the conditions at Boulevard Homes, many tenants' wish to live in a private rental home, and the fact that higher incomes improve most people's quality of life.

In contrast to these results, however, households that reported better overall quality of life were also more likely to report that they had run out of food in the past 12 months. This outcome is most likely due to the additional costs associated with renting a private home

rather than living in public housing. Also, individuals in this group may have been making enough money to lose benefits such as Medicaid and to have their food stamp benefits reduced.

Overall, the quantitative data supports our hypothesis that moving mothers with dependent children from a highly distressed public housing does improve the lives of many households. Moving with the support of an HCV was fully predictive of households reporting a much better overall quality of life. Also, most households reported feeling safer after relocation, which also positively impacted quality of life (see Table 7).

Despite these gains, the data did not reveal significant improvements in any of our measures of health. This may be related to the size of the sample but is most likely due to extremely poor health within the sample. The move and provision of community supportive services may be insufficient to alter the course of the adverse childhood experiences that have already marked the health of mothers and other caretakers within our sample.

Qualitative Results

Qualitative results confirm and expound on the quantitative findings. The top four responses to the open-ended survey question asking about the "best things about moving away from Boulevard Homes" (see Table 8) included having a better house (29%), living in a situation that is better for their family (18%), living somewhere that is safer with less violence (15%), and living in a better neighborhood (14%).

In describing what is best about her new home, one resident captured the sense of relief that comes from moving to a neighborhood that is safe and a home that is devoid of environmental toxins, "New surroundings, very pleasant place to live. I am more comfortable. Enjoy the neighborhood and I am also more [able to] relax." Another respondent referenced the difference in the property crime rate in her new neighborhood compared to Boulevard Homes: "Being in a house where my kids have a yard of their own to play in with no worries about their bikes being stolen." One mother wrote that, "My children was able to graduate and receive some college without the Boulevard Homes influence." Others were more succinct, writing, "Better for my kids" and "Don't have to deal with the high crime rate."

In responding to "the worst things about moving away from Boulevard Homes," 21% could not name any negatives associated with the move. However, some wrote that they had more expenses ("Having to pay more than one bill"), regretted moving away from friends, family, and familiar places, ("The neighbors are truly missed. I worry about the children and wonder how they are getting along"), or complained that they were forced to select housing or a neighborhood that was no better than Boulevard Homes ("Bad heating problem in this home. Can't find a home that is decent with accepting voucher amount").

Those who reported that their lives were "not much better" after relocating from Boulevard Homes reported higher social capital scores in 2010 (a mean of 0.41 vs. 0.3) and seemed to feel safer while living there (a mean of 2.9 vs 2.33) than those whose lives were much better. This group experienced greater social cohesion within Boulevard Homes and didn't feel the same sense of urgency for their personal safety. Increased expenses and less responsive landlords also made the move difficult for some.

While the open-ended survey questions confirm the quantitative findings that improved housing and neighborhood conditions are important to well-being, the interviews provided compelling stories about the fear and anxiety that came from living in Boulevard Homes. In their stories, we see clear evidence of the development of toxic stress among some of the mothers and accumulation of adverse childhood experiences (ACE) among the children.

Dania is a Black woman in her mid-fifties with an eight-year-old son. She uses a motorized wheelchair after rheumatoid arthritis disabled her in her forties. She moved into Boulevard Homes after she was disabled, could no longer work as an industrial restaurant kitchen manager, and became pregnant with her last son. She lived at Boulevard for five years during her pregnancy and then, after he was born, for roughly the first four years of his life.

When we met, she was quick to tell us that her life has been “excellent [since moving away from Boulevard Homes because she is no longer] around drug lords or in between drug battles.” She recalled “My car was shot up, like 18 times, had 18 bullet holes in it, and it got broken into like ten times.” She continued,

I have to praise God because even though the car was broken into and shot up, we were never broken into and none of those bullets ever came through our house to injure me or my sons. So I was blessed but still it was traumatic. Every night. Every night. I really still don’t sleep at night

Living at Boulevard Homes was a traumatic and potentially deadly experience for Dania. One Sunday morning she headed out of her apartment with her son, who was two at the time, when they were confronted with a young man brandishing and shooting a handgun. “Going round and round in a circle, shooting. He shot four people that day... And I’m trying to get to my child, I’m running to get him.” She finished her story telling us that she managed to grab her son, get in her car, and drive away to the safety of family. “It was something every day. I have not had any incidents, traumatic incidents like that, since I’ve been in my house.”

Table 8. Qualitative Response Categories for Best and Worst Things about Moving from Boulevard Homes

Best Things About Moving	
Reason	# (%)
Better house	25 (29)
Better for family	15 (18)
Safer/Less violence	13 (15)
Better neighborhood	12 (14)
More convenient location and better transportation	11 (13)
Better neighbors	9 (11)
Peace and quiet	6 (7)
Greater independence and privacy	5 (6)
Relocation support provided	5 (6)
Nothing	12 (14)
Worst Things About Moving	
Reason	# (%)
Poor housing quality	15 (19)
Missing family and friends	11 (14)
Relocation process and expense	11 (14)
Inconvenient location	10 (13)
Neighborhood and/or neighbors are bad	10 (13)
More expenses	9 (11)
Nothing bad about moving away	17 (21)

Her new home includes a back yard for her son, a space for him to play basketball, and a big front yard where she has planted flowers with her next-door neighbor who has become a good friend. She describes her new home as "really serene ... gardening, peace, to be able to sit on my front porch in the morning and just be at peace."

Kathy also shared a story of fear while living at Boulevard Homes. She is a White woman in her late sixties who is disabled by obesity, diabetes, and a heart condition. She told us that she worked fulltime her whole life until she had a heart attack. She used the HCV to move outside the city to a small house close to where she grew up and raised most of her five children. She shares the house with her adult daughter, Mary, who is in early thirties, and her daughter's three children ages 17, 8, and 2 years. Although the house is somewhat crowded, Kathy is committed to continuing to live with her daughter and grandchildren. Her daughter was diagnosed with bi-polar disorder and borderline schizophrenia. The family moved to Boulevard Homes after their home burned down.

When we asked her if their lives are better or worse since leaving Boulevard, she told us, "This is better. This is where I grew up. I know everybody. It's more comfortable." She continued,

I didn't like living in Boulevard Homes, 'cause I never lived in that type of environment before. Drugs and shootings and killings. When we were there, eight people got killed...Yeah, people got killed while we lived there. One right across the street and one on the corner across the street from us. The only time I come out of my house was to go to work or to the grocery store. I didn't get out to socialize with people

The children also had a hard time while living at Boulevard. Their mother became involved with drugs, developed an addiction, and the two children she had at the time were taken into child protective services custody. Eventually, the children were returned to the family's custody. Kathy told us that the children didn't like living at Boulevard Homes. "[The eldest child] couldn't ride her bicycle 'cause you never knew what was going to happen over there."

Kathy differentiates the experience of being poor from being poor and living in an environment like Boulevard Homes. "We grew up in the mountains. We were so poor! I can adjust to just about anything ... except killings. ...I was scared over there."

Five years after leaving Boulevard, the family seems to have stabilized. The oldest daughter was preparing to graduate from high school. The middle child was doing well in middle school and the two year old displayed all the developmentally appropriate behaviors of a two year old. The HCV has given Kathy an opportunity to return home to a place she feels safe and that she believes will be a better environment for her daughter and grandchildren. "I like it out here, 'cause it feels like coming home."

Although Dania and Kathy are only two of the 13 former Boulevard Homes parents we interviewed, their stories are not atypical. Many of the families interviewed had suffered some major setback in their lives that necessitated the move to public housing such as a significant health problem, domestic violence, or loss of a home. Public housing would not have been their first choice but it offered what they believed would be a safe and affordable refuge at a time of crisis in their lives. And while not all of the women we spoke with told such vivid stories of the violence and fear experienced while at Boulevard Homes, all of them believed that moving away from Boulevard was better for their children.

Dania and Kathy also referenced the social isolation they felt while living at Boulevard Homes. Although most of those we interviewed indicated that they had made some friends while living in the public housing community, their interactions were severely limited by the fear they experienced while living there. It was common to hear that the former residents had made new friends in their new neighborhoods.

For most of those interviewed, a sense of safety and peace were the overwhelming advantages to the move from Boulevard Homes. Most also found their new residences were of better quality and in better condition.

DISCUSSION

What emerges from the quantitative and qualitative data confirms that residents living in Boulevard Homes were exposed to violence, social disorder, and poor quality housing. The parents and caretakers indicated high rates of chronic physical illness and disability and experienced high rates of depression and anxiety. The children living there were exposed to these same negative experiences but were placed at greater risk as a result of their developmental vulnerabilities and their caretakers' fragile physical and mental health.

Our findings are consistent with other studies of HOPE VI [20]. Prior to relocation, the Boulevard Homes residents suffered multiple measures of social distress: low educational attainment, high unemployment, and poor health. They experienced statistically significant improvements in perceptions of increased safety, and overall quality of life was improved by moving to better housing and neighborhoods with the use of a housing choice voucher (HCV). These results were tempered, however, by the additional costs associated with living in private rental housing. These findings confirm our hypotheses that adults who express satisfaction with their housing and reductions in their fear of crime will experience improvements in an overall measure of well-being.

Consistent with other studies, heads of household did not make major gains in their education, employment, or health while receiving community supportive services [25, 26]; however, they experienced slight improvements in some of these measures including employment and income [3, 25]. The adults in our sample continue to report extremely high rates of chronic physical and mental health conditions. The move to better housing and a better neighborhood improved feelings of overall well-being and seems to have reduced some symptoms of anxiety and resulted in slight increases in individual's access to social capital.

The move did not, however, reduce depression scores and could not alter a diagnosis of rheumatoid arthritis or reverse a chronic heart condition. The high percentage of tenants who moved with an HCV meant that many individuals in our sample were more likely to have moved to better neighborhoods and better quality housing. This also means, however, that the household assumed increased expenses associated with private rental and that they were more likely to have been separated from family and friends and easy access to public transportation. Boulevard residents who were older at the time of the move and who had fewer financial resources were more likely to experience reductions in their overall quality of life due to these factors of expense and location.

It is also important to note that not all relocatees reported lives that were "much better" after leaving Boulevard Homes. This finding is also consistent with other research on HOPE

VI relocations [25, 26]. Some of the households relocated from Boulevard Homes had lived there most, or even all, of their lives. Although flawed, Boulevard Homes represented a familiar community, and moving separated these householders from people they cared about and, in some cases, a neighborhood and resources they knew. Moving is a highly stressful event for most individuals and is more so when those affected have few resources.

Children under the age of 19 years comprise 55% of those affected by the move from Boulevard Homes, and 75% of these children were aged 12 years or younger at the time of the move. Given the research regarding the developmental and physical effects of toxic stress and biodevelopmental vulnerabilities, this age pattern suggests reasons for both concern and optimism. The experience of living at Boulevard is cause for concern because women who were pregnant while living there were exposed to environmental toxins, potential physical injury, and the likely neurophysiological effects of prolonged and extreme stress. Also, children exposed to the hazards of highly distressed housing and neighborhoods have the potential to be negatively affected, the stressful experiences becoming biologically embedded and making them susceptible to disease and negative behavioral responses. Mothers who were depressed and stressed while living at Boulevard would have been more likely to engage in inconsistent or neglectful parenting, increasing the likelihood that the children would have experienced more ACE. Outside the home, the children would also have been exposed to the violence and social disorder of Boulevard Homes.

Despite these concerns, many of the children who were under age 12 years at the time of the move had the opportunity to attend different and better schools and to experience their teen years in neighborhoods that were less isolated and socially dysfunctional. The timing of the move also indicates their exposure to the Boulevard homes and neighborhood environment would have been of a shorter duration, suggesting that they potentially experienced fewer ACE and environmental toxins. Finally, this group of children is also more likely to benefit from the educational and employment outcomes that emerged from the more recent evaluation of the MTO data [19].

Limitations and Next Steps

Neither the HOPE VI program nor our surveys were designed to directly address trauma or toxic stress in either caregivers or their children. However, these topics emerge in both the quantitative and open-ended survey data and in the interviews held with residents. Conclusions about the well-being and trajectory of children impacted by living in Boulevard Homes and the subsequent move must also be inferred as both the surveys and interviews were conducted with the head of household who is the child's caregiver. As there is substantial evidence linking caregiver well-being to child outcomes [1, 4, 7–9, 17–19, 21, 26, 28], we feel this is not a significant limitation on our conclusions and recommendations. In future research, we hope to link this data to Charlotte-Mecklenburg Schools' data to better understand how the move away from Boulevard Homes and to better housing and neighborhoods affected the educational outcomes of the children.

Finally, this study did not demonstrate statistically significant improvements in any of our measures of health. Extremely high rates of trauma exposure and disease burden within this sample may be obscuring statistically significant improvements in some of these

measures of mental health [26]. Despite this, interviews suggest parents and children did experience meaningful improvements in their overall sense of well-being linked to feeling less anxious and depressed.

Recommendations

While the last HOPE VI grants were awarded in 2010, lessons learned from the program and this study can provide valuable insight into intervention programs for other highly vulnerable families living in public housing. The new Housing and Urban Development grant initiative, Choice Neighborhoods, incorporates many of the lessons learned from HOPE VI by seeking to improve overall housing and neighborhood quality to increase the economic mobility and well-being outcomes of public housing residents [29].

HOPE VI has made a significant and positive impact on the eradication of severely distressed public housing and has funded the construction of units that not only provide “defensible space” but are also intended to encourage positive interactions between neighbors of different income levels. The new units are built with environmental health in mind and many ban smoking. Perhaps most significant, efforts have been made to increase the physical safety of residents through careful screening of applicants, strict enforcement of rules of conduct, and enhanced surveillance of public space. All of these measures should help to improve the physical and mental well-being of residents [25].

Individuals and families who qualify for public housing are at high risk for health disparities due to their poverty status, race, and previous exposure to trauma [8, 30]. Adults living in public housing are less likely to have completed high school or to have completed additional education and training [27]. Poverty and low educational attainment are two of the greatest risk factors for chronic mental and physical health disease [8]. Interventions that help adult residents increase their educational attainment and obtain better quality higher paying jobs are not only strategies to improve economic mobility but also strategies to improve health and well-being [7, 22, 26].

Housing authorities and communities have an opportunity to intervene in the cycle of poverty. Fifty-five percent of those living in Boulevard Homes at the time of the relocation [27] and 37% of all those living in public housing nationally [30] are children under the age of 19. These children are highly vulnerable to poor outcomes in education, health, and employment [1, 7], however, they also have access to a vital resource – safe and affordable housing [22, 24, 28].

In addition to ensuring that families have safe housing and neighborhoods that protect residents from environmental hazards, the delivery of targeted programs to address mental and physical health, and educational and employment deficits will improve the outcomes of public housing residents [7, 22, 24]. Housing authorities and community stakeholders are well aware of the significant needs of this population and of the significant costs incurred when these deficits are not effectively addressed [5, 9]. In particular, families with young children represent an important opportunity to halt the cycle of intergenerational poverty and health disparities [1, 4, 7]. Partnerships that provide early childhood interventions such as pre- and perinatal care, nutrition assistance, parenting support to improve developmental and educational outcomes, and preschool have all been found to be highly effective at improving

the outcomes for these children and families [22]. Intervening in the cycle of health disparities will produce a lasting and intergenerational effect [4, 8].

If public housing authorities prioritize addressing the health needs of their residents, they will not only improve the health of residents but also increase the economic mobility of the entire household [22, 24]. As the health, well-being, education, and income of the household increases, so too, does the likelihood that children living in the homes will escape the cycle of environmental disparities, ACE, and toxic stress that limits their future and the future of their children [4, 8].

Chapter 23

LEARN, EAT, GROW: THE HEALTHY LIVING INITIATIVE

Maya Bornstein*

Sociology Department, College of Arts and Sciences, Emory University,
Atlanta, Georgia, USA

ABSTRACT

In order to address the health disparities and challenges resulting from the unequal availability of healthy, fresh, affordable food in the Greater Atlanta area, we implemented an intervention for school children to encourage better nutritional choices. This entailed a six-week partnership with a local school introducing a curriculum geared toward gaining knowledge about healthy food and lifestyle options, through the means of urban gardening. Students were surveyed regarding their dietary intake and knowledge regarding nutrition and gardening before and after the intervention. The six sessions included curriculum centered on gardening, cooking, exercise and components of a healthy lifestyle and encompassed hands-on-sessions regarding tasting, cooking, and growing vegetables and herbs. Surveys prior to the start of the intervention confirmed that students in this metropolitan Atlanta classroom were not knowledgeable about dietary recommendations and consumed below the suggested daily portions of fruits and vegetables. At baseline, few knew basic nutritional facts and 56% of students reported that they had never previously had a gardening experience. The average number of fruit and vegetables consumed daily was 2.7, ranging from none to 7. After the six educational sessions all but two students out of 33 knew the recommended daily intake of fruit and vegetables, and their average reported intake rose from 2.7 to 3.2 servings. Every student could name three healthy snacks, and at least two benefits of gardening. Teaching about healthy living and gardening during this six-week period led to an increase in the consumption of fruit and vegetables and a greater knowledge regarding healthy eating, and gardening.

Keywords: urban gardening, food deserts, nutrition, healthy choices, intervention

INTRODUCTION

Lack of access to healthy fresh food contributes to the cycle of health disparities and obesity facing lower income children in inner city America. The aim of this project was to break the cycle of health disparities resulting from poor understanding of nutrition and limited access to nutritious foods. As a pilot study, an intervention was planned and executed targeting high school students in inner city Atlanta, Georgia.

Disparities in Atlanta and Food Deserts

Several economic, social, and health disparities plague the Atlanta area. Eighteen percent of Georgia's residents live at or below the poverty line, which is an increase of almost one million more people experiencing poverty since 2000 [1]. Twenty-eight percent of Georgia's children live in food insecure households, and cannot afford to buy healthy food on a regular basis [2]. This leads to what is known as a "food desert." A food desert is an urban area in which it is difficult to buy affordable or good-quality fresh food [3]. There are many factors that contribute to food deserts, including environmental factors that affect local growing efforts such as soil, climate, and space, behavioral factors which impact communities' acknowledgement of food related issues in their area and educational factors that reflect consumer's knowledge of healthy food choices. A food desert results from limited food options, supermarket wars, and the lack of knowledge and choice when it comes to food choices, especially in lower income areas. Food deserts contribute to increasing obesity rates, as well as unhealthy eating habits because of limited access to fresh and or affordable produce. Access to fresh food is strongly correlated with economic status and low income communities have limited access to healthier food options [3]. This statewide issue is reflected at the local level in Atlanta where significant gaps in neighborhood food availability exist. There are 35 food deserts located inside Atlanta's perimeter, impacting two million Georgia residents, including 500,000 children who live in food deserts [2].

Urban Gardening

The concept of urban gardening is that fresh food can be grown locally, even within the confines of the city. Urban gardens are focused around cultivating, processing and distributing food in a town or city setting, making the necessary accommodations in order to grow produce in an unconventional agricultural setting. Urban gardening has been shown to help combat food deserts [4]. Urban gardening also has been shown to promote greater community collaboration while producing home grown, healthy food that is accessible and affordable [5, 6].

Previous Cases Studies

Previous studies have shown that urban gardening increases nutritional food intake and helps individuals develop an appreciation and knowledge of healthy habits. Urban gardening increases children's connection with their food, which results in an improved awareness of the nutritional content of the foods that they eat. It introduces them to new choices, allowing them to gain access to healthy fresh food that in many areas are difficult to obtain. Urban gardening brings communities together, can reduce crime, and promotes obtainable healthy life options [7].

According to an article entitled "A garden pilot project enhances fruit and vegetable consumption among children" [7], children who grow their own produce are more likely to eat healthier, because they are connected to the food they grow. They describe a program titled "Delicious and Nutritious Garden" created in Emmaus, Pennsylvania. During the course of this 12-week program, 4th through 6th graders worked in a garden and created healthy snacks out of the produce they helped to cultivate. By the end of the study, they found that, "98 percent of kids said they liked the taste tests, 93 percent said they liked the cooking aspect, 96 percent liked working in the garden, and 91 percent said they actually enjoyed learning about fruits and vegetables". This form of "seed-to-table" program was shown to be successful and engaging for the children. The study demonstrated that the gardening program led to better eating habits for the participants, and that this "hands-on" learning approach presented the students with a cost effective way to grow food, instead of relying solely on items available in the grocery store [8].

Another example of an effective intervention was conducted by Stephen Ritz, a teacher based in the Bronx borough of New York City. Ritz addressed the problem of food deserts in his area by addressing the food desert by teaching students how to grow produce. He turned his classroom into the National Health, Wellness, and Learning Center. An article in the Wall Street Journal describing his project states, "We're harvesting hope and cultivating minds" in the Bronx neighborhood where his school is located [9]. Ritz and his students helped create urban gardens throughout the Bronx, even in classrooms. He taught his students how to grow and cook with fresh produce. Ritz's goal was to "send students home with 100 bags of fresh, school-grown fruits and vegetables a week, 50 weeks a year." These students often did not have enough food at home in general, and they had no prior experience with organic fruits and vegetables [9, 10].

Another study conducted in Lawrence Massachusetts focused further on the role of urban gardening in nurturing community ties and reducing inner city violence [11, 12]. The author concluded that "Community garden programs can strengthen civic engagement and foster neighborhood stability, while simultaneously cut down on youth violence [11]"

Nutritional Education

There are many resources regarding good nutritional choices available; however, many educators and students do not know how to access them. These resources are rarely used in a school setting. Such tools include Choose My Plate [13], the Environmental Protective

Agency (EPA) guidelines [14], and local area gardening initiatives. These tools can be used to educate individuals as to a balanced and healthy lifestyle.

ChooseMyPlate is an initiative of the United States Department of Agriculture's (USDA) Center for Nutrition Policy and Promotion. Its two primary goals are to "advance and promote dietary guidance for all Americans, and conduct applied research and analyses in nutrition and consumer economics." ChooseMyPlate provides information regarding how to prepare a healthy meal, and the daily servings recommendations for each of the major food groups; fruit, vegetables, grains, protein, and dairy, based on age and body mass index [13].

The purpose of the United States Environmental Protection Agency is to develop policies to protect human health and the environment. The EPA has been working to create a lesson plan designed to engage and excite children about different forms of environmental health, and to empower them to take action in their communities to lessen the many environmental risks that they face. The students learn about environmental health and how to positively impact their communities through an "Ask, do, and explain" campaign with hands-on learning [14]. This program is very promising, however it is not yet implemented nationwide, and many school districts are unaware of this resource.

Education is necessary to improve dietary habits. Poor nutrition is a factor in the high rates of obesity and heart disease in America [15].

Community gardens are another means to engage participants in a "real life" educational experience. These gardens bring people together, have the potential to reduce crime in "high-risk" neighborhoods, and produce fresh fruits, vegetables, and herbs for the whole community to enjoy [11]. Efforts at urban agriculture such as community gardens improve food security and safety. The growers are involved in the entire process, from the soil and seeds to harvesting the end product. Community gardens reduce the carbon footprint, while teaching city residents about agriculture and how to achieve a nutritious food balance [16].

METHODS

Participants: Druid Hills High School was identified as an ethnically and socioeconomically diverse Atlanta public school located in close proximity to Emory University. In 2015, enrollment in this school included 1,353 students. Fifty percent of the student body is self-described as African American, 23% as White, 12% Asian, 10% Hispanic, and 4% as Multi-racial [17]. The school administration agreed to participate in the study and proposed conducting the intervention in a science course, after consultation with the science department. The participants in the project consisted of 33 ninth grade biology students at Druid Hills High School. The gender composition of the classroom was 52% female, 48% male, and students were 14 to 15 years of age. High School students were chosen as participants because the topic was compatible with their curriculum.

An Institutional Review Board exemption was obtained from Emory University. However, since the participants were minors, consent forms explaining the project were distributed and signatures were obtained from both the students and their parents.

Description of survey: Two surveys were administered to the students, a preliminary survey before the intervention began, and a concluding survey to evaluate the impact of the intervention. Baseline eating and gardening habits and knowledge about nutritious eating was

assessed. Demographic information regarding age and gender were collected. Students were asked how many fruits and vegetables they consumed daily, as well as the specific number consumed during the past 24 hours. Participants were asked if they had any prior gardening experience, and surveyed regarding their favorite foods, allergies, and previous experience with home grown foods. The final survey included similar questions regarding both knowledge and habits related to maintaining a well-balanced lifestyle and the benefits of urban gardening. It also questioned students as to how they would act in the future regarding food choices and whether or not they found the intervention to be worthwhile.

Intervention: The intervention was conducted over a six-week period, and the investigator visited the classroom once a week, interacting with students during their science class period. The six-week lesson plan included instruction regarding the growing of plants and gardening. Students were taught the importance of making healthy choices. During the first week of the intervention, students answered the initial survey, and planted one of the following vegetables/herbs in a compostable seed-starting container; snap peas, basil, dill, or lavender, with store-bought all-purpose gardening soil. Herbs were selected for the project because they grow rapidly and require relatively little intervention. During the second week they learned about the national food plate, which corresponds with the recommended daily food intake of fruits, vegetables, protein, grains, and dairy, as well as how to incorporate these foods into everyday meals. During the third week they prepared and sampled healthy snacks including non-fat yogurt parfaits with granola and fruit, edamame, apple slices with cinnamon, and guacamole. In session four they learned about the components of a healthy well-balanced life, as well as the cost effectiveness of growing fruits and vegetables. During week five, the students helped to start a school garden outside, and played games that promoted physical activity. For the last session, students brought in healthy recipes that were compiled to make a class cookbook. They also reviewed all that they had learned, took the closing survey, and received seeds to enable them to continue their gardening efforts at home.

Throughout the six weeks, the seeds planted during session one were tended to by providing them with water and sunlight. Students brought the plants home on the final day of the intervention.

Data Analysis

Surveys were distributed to the study participants prior to the intervention and again following the intervention. The results were compiled by the primary investigator. Quantitative results were examined in Excel spreadsheets and presented graphically. The responses to qualitative questions were analyzed and recorded independently. Qualitative answers were categorized based on the extent of nutritional knowledge demonstrated. For example, students were asked to name three benefits of urban gardening. If they provided these items correctly, they received a score of one, and if they were unable to do so. They received a score of zero.

RESULTS

The data collected from the preliminary and final surveys were analyzed independently and then the results were compared to assess the effectiveness of the intervention.

The results of the initial survey indicated that 56% of the students had no prior gardening experience. The preliminary survey revealed that the average number of fruits consumed per day by the students was 2.3 servings. The average number of vegetables consumed per day was 2.0 servings. The average number of fruits and vegetables combined eaten by the students in the previous 24 hours was 2.7 servings, ranging from none to 7. The results are shown in Figure 2. Few participants knew the correct recommended number of daily servings of fruits and vegetables. The students' favorite foods included choices ranging from salads to jelly beans, and the foods varied vastly in nutritional value.

Learn, Eat, Grow: Initial Survey

Name (First and Last Initial): _____

Age: _____

Gender: _____

What is your favorite food?

Are you allergic to any foods? Yes / No

If yes, which foods?

How many fruits do you eat per a day?

How many vegetables do you eat per a day?

How many servings of fruits and vegetables are you supposed to have every day?

Which fruits and vegetables have you eaten in the last 24 hours?

Have you ever had a garden?

Have you ever eaten homegrown fruit or vegetables? If yes, which ones?

LEARN, EAT, GROW: END SURVEY

Name: _____

Age: _____

How many fruits do you eat per a day?

How many vegetables do you eat per a day?

How many cups of fruits and vegetables are you supposed to have every day?

Which fruits and vegetables have you eaten in the last 24 hours?

Can you name 3 healthy snacks?

Do plan to start a garden in the future?

Name 2 advantages to creating homegrown food:

Did you enjoy this project? Why?

What was your favorite class session? Why?

What was your favorite class session? Why?

What would you change or improve about this project?

Figure 1. Learn, Eat, Grow surveys.

After the six educational sessions all but two of the 33 students knew the correct recommended daily number of serving of fruit and vegetables per day (see Figure 3). The survey revealed that after the intervention, the average number of servings of vegetables consumed per day increased from 2.0 to 2.6. The concluding survey also showed that after the intervention the average number of servings of fruits consumed increased from per day 2.3 to 2.4, which does not reflect a significant change. However, when specifically queried regarding their intake of fruits and vegetables during the 24 hours prior to the survey, the results reflected a change from 2.7 to 3.2 servings (see Figure 4). Every student could name three healthy snacks, and at least two benefits of gardening. Forty-one percent of students wrote that they definitely would like to start a garden in the future; whereas, before the study half of the students were not at all familiar with home-grown food.

Figure 2. Preliminary survey: Fruit and vegetable intake in the previous 24 hours.

Figure 3. Concluding survey: Fruit and vegetable intake in the previous 24 hours.

Figure 4. Students regarding their intake of fruits and vegetables 24 hours prior to the survey.

The participants reported that their favorite classes included the sessions when they planted their own herbs, learned about nutrition and prepared healthy snacks, and helped to create a school garden. All of the students reported that they enjoyed participating in this project and they praised its implementation in the classroom. Overall, healthy food intake increased, albeit not dramatically, and so did their knowledge regarding nutrition and

gardening. The intervention showed a positive trend of increased knowledge and participation in maintaining a healthy lifestyle and developing a connection and awareness about homegrown fruits and vegetables.

DISCUSSION

This project adds to existing literature on the subject of urban gardening and nutritional choices and suggests that simple interventions can make a difference in improving healthy living. Other studies have similarly demonstrated the impact of the introduction of gardening to school aged children, but these were generally conducted over longer time periods. For example, a model study performed in Minneapolis evaluated an urban gardening program that continued for 12 weeks [8]. A project conducted in five elementary schools in Texas involved introducing growing vegetables throughout the school year [18]. They observed an increased appreciation and consumption of fresh produce as a result of the project.

Figure 5. Break the Cycle Chart.

From this study, it appears that even after six weeks learning about urban gardening and nutrition had an impact on 14 to 15-year-old school children. As their understanding of these issues grew, they began to consider healthier choices. The project increased nutritional

awareness, which resulted in the ability to make healthier food choices. The positive results of this and other pilot programs suggest that the implementation of larger and longer interventions in schools could have a significant impact.

The strengths of this study included the successful engagement of the students and the collaboration of dedicated teachers. A highlight of the intervention was that students actively participated and wanted to learn more. Some students came to the primary investigator eager to share new healthy recipes that they had identified, and others expressed their eagerness to continue to grow plants.

Unfortunately, this six-week project did not provide enough time to plant and harvest fruits and vegetables. Future project should be at least three months long to allow a full harvest cycle [19]. During this intervention, students planted herbs. In order to develop a deeper connection to their produce, it would be ideal if the children were able to plant other fruits and vegetables. For example, focusing on a vegetable such as the zucchini squash would enable the students to learn to grow a product with nutritional value that could then be introduced in numerous recipes.

The investigators were not able to evaluate how race or income influenced the students' access to and knowledge about healthy eating. This data was not available for analysis.

High school students were chosen for this program because they are more able to make independent diet choices compared to younger children. The topic of the study fit in well with their biology curriculum, because students could relate what they were learning about health and nutrition with other concepts taught in class [20].

During the time that this project was conducted other issues came to light. The school meals were noted to consist of unhealthy processed foods, and fruits and vegetables used were often canned or frozen. A greenhouse has been proposed to allow year round gardening and access to fresh produce. The school has set aside dedicated garden space in front of the school, which will facilitate the continuation of the basic concepts of gardening introduced in this project. The school and especially a few dedicated teachers have embraced the urban gardening initiative and look forward to future collaborations. Based upon the success of this pilot intervention, the faculty is interested in possibly adding similar units to the school curriculum in biology and environmental science courses.

ACKNOWLEDGMENTS

The preparation for this paper and the Healthy Living Initiative was supported by the Southeast Pediatric Environmental Health Specialty Unit and Innovative Solutions for Disadvantage and Disability: Break the Cycle Program.

Chapter 24

SHOULD PARENTS BE ALLOWED TO REFUSE VACCINATIONS FOR THEIR CHILDREN?

Dilip R. Patel*, MD, MBA, MPH and Kelly A. Brown, MD

Department of Pediatric and Adolescent Medicine,
Western Michigan University Homer Stryker MD School of Medicine,
Kalamazoo, Michigan, USA

ABSTRACT

Vaccine hesitancy and parental refusal to vaccinate their children have been a subject of vigorous debate, especially in the United States, where the incidence of vaccine preventable diseases is low. In addition to medical contraindications, vaccine refusal based on personal philosophical or religious beliefs poses challenges to sustain effective mass immunization programs and herd immunity. In United States, where, recommended childhood vaccinations are mandated to attend school, a question often raised is, “Should parents be allowed to refuse vaccination for their children?” This article explores some basic ethical and practice implications implicit in this question.

Keywords: vaccine, immunization, parental rights, herd immunity, Gilovich’s taxonomy, free-riding

INTRODUCTION

A vast array of factors including geographic, political, economic, disease epidemiological, cultural, and other local factors influence health behaviors of people in different parts of the world, including parental attitudes towards vaccination for their children. Therefore, this discussion is limited to issues regarding vaccination of infants and children in the United States.

* Corresponding Author’s Email: Dilip.Patel@med.wmich.edu.

PARENTAL RIGHTS

Do parents have the right to make medical decisions for their children? In the United States, most vaccinations are given during infancy and early childhood. It is generally agreed that at this age, children, because of their limited cognitive maturity and life-experiences, are not considered competent to make medical decisions for themselves [1, 2]. Therefore, the law grants parents (or other legal guardians in some cases) the right to make medical decisions for their children. In that sense, the legal rights of parents, under most circumstances are clear regarding their right to make medical decisions for their child.

In addition to the legal rights, what are other considerations for parental rights? In medical decision making, it is widely accepted that one must consider any decisions based on the best interests of the patient. Physicians apply this logic in their daily practice when faced with multiple choices in management decisions for their patients. The same argument can be extended to the issue of parental decisions for their children. It is generally agreed upon that parents make medical decisions for their child based on what is in the best interest for the child. It is important to recognize that in this case what constitutes best interest for the child is determined by parents, and that others may disagree with parental reasoning.

Dawson [2] has explored the issue of “best interest” in relation to childhood vaccinations. According to Dawson [2], there are two main views of what constitutes “best interests,” namely the objective view and the subjective view. Based on the objective view, the concept of best interests is explained in terms of maximizing the individual welfare, well-being, or good. Such a determination of best interests can be arrived at independently of what the individual might believe or desire to be relevant to be maximal welfare or well-being. Taking this view, “...the judgment as to what is in an individual’s best interests is to be determined by the outcome which would maximize welfare, even if we are ignorant or mistaken about which outcome that might, actually be” [2]. On the other hand, taking the subjective view of best interests, “...the concept is to be defined in terms of what the individual themselves does choose, or if they are incompetent, what they would be expected to choose if they were able to do so” [2]. In addition to legal rights and best interest considerations, the parental right to vaccinate or not to vaccinate their child is also considered on the basis of ethical principles of respect for autonomy and individual right to privacy [3].

REASONS FOR PARENTAL REFUSAL OR HESITANCY TO VACCINATION

Given that parents have the right to make medical decisions for their child, they have the right to make decisions about vaccination for their child, including the right to refuse to vaccinate. Thus, it is important for medical professionals to understand why parents are hesitant or refuse to vaccinate their child.

Parental perspectives and attitudes on vaccination are influenced by a complex interaction of medical, social, personal, and religious factors [4, 5]. Parents may be hesitant or refuse to allow vaccination for their child on the basis of medical information they have received from various sources including medical professionals, public health agencies, and the media [1, 3]. The scientific accuracy of such information, how such information is

communicated or presented, and how it is interpreted by parents influences their decision [6, 7]. Parental trust or mistrust of various sources of information is also an influential factor. Healthcare providers should provide evidence-based, unambiguous information for parents regarding vaccination, addressing any specific fears or concerns. Providing information about vaccine preventable diseases, morbidity, and sequelae in an honest and open manner is important for parents to understand the potential risks of refusing or delaying immunization for their child [6, 8, 9].

Well established medical conditions or diagnoses for which certain vaccines are contraindicated are not the main subject of contention. However, there are numerous parental fears and misconceptions regarding vaccines that in general do not outweigh the benefits of immunizations. These fears or misconceptions include: fear of pain or discomfort of the child, concern for potential ill effects on child's immune system from multiple immunizations, belief that acquiring "natural" immunity is healthier by contracting the vaccine preventable disease, or belief that some vaccines are not as important as others. In other cases, parents may fail to grasp the seriousness of vaccine preventable diseases because they have not encountered them in daily life or the perception that vaccine preventable illnesses are uncommon in the United States.

Parents or caregivers may also truly believe that there is no need for their child to be immunized because the majority of other children are, and the chances of contracting a disease is very low (as in "herd immunity"). In this case, some may believe that the purported benefits of vaccination do not justify the potential risks to their child. Objections to immunizations that are based on parental understanding of available information can be addressed adequately in medical practice. However, objections to vaccination based on personal religious or philosophical beliefs, or based on principles, pose significant ethical dilemmas and public health challenges, and is the subject of much debate.

RELIGIOUS OR PERSONAL OBJECTIONS TO VACCINATION

Grabenstein [10] in a review on religion and vaccine practices identified more than sixty reports or evaluations of vaccine-preventable infectious disease outbreaks that occurred within religious communities or that spread from them to broader communities. He found that the religious reasons to decline immunization reflected concerns about vaccine safety or personal beliefs among a social network of people organized around a faith community, rather than theologically-based objections per se. This is an important consideration when evaluating religious objection to vaccinations.

In the review of reasons for vaccine refusal, Jacobson et al. [11], found that flaws in personal reasoning and information interpretation played a role in decision making. Jacobson et al. [11] also cited the work of Gilovich [12] to provide the basis for such flaws. The Gilovich's taxonomy [12] of common flaws in reasoning include the cognitive determinants (desire to find order and predictability in random data, difficulty in detecting and correcting biases in incomplete and unrepresentative data, eagerness to interpret ambiguous and inconsistent data to fit theories and expectations) and motivational or social determinants (wishful thinking and self-serving distortions of reality, pitfalls of second-hand information

and miscommunication including mass communication, exaggerated impressions of social support).

ETHICAL IMPLICATIONS OF PARENTAL REFUSAL TO VACCINATE THEIR CHILDREN

First, what are the implications of parental refusal to vaccinate their child? For the child, one might consider the obvious risk of contracting the vaccine preventable disease. From a public health perspective there is the risk for spreading the disease to others who are not immunized for various reasons. There is also the risk of reducing herd immunity and thereby diminishing the overall protection from the disease for the community.

According the American Academy of Pediatrics, pediatricians should respect parental decision not to vaccinate their children and engage in an ongoing dialogue to address their concerns about vaccines [1]. AAP considers a pediatrician's decision to dismiss family from further care on the basis of vaccine refusal as an option. However, if access to care for children whose parents refuse vaccinations is limited, the AAP recommends caution against dismissing them from practice [1].

At present time, given that under most circumstances the risk of contracting a vaccine preventable disease is very low from those who are not immunized, one can invoke the harm principle [3]. Based on the harm principle, parents may refuse vaccination because such a decision does not pose substantial risk to others in a highly immunized population such as that in the United States.

In considering parental vaccine refusal, the issue of "free-riding" has also been discussed in the literature [3, 13-16]. "Free-riders" are individuals who benefit from programs in which they have not contributed. Free-riders benefit from conditions created by individuals in the community who have contributed and participated to create the beneficial conditions in the first place. These individuals therefore have not taken any risks associated with a given action that others in the community have. In consideration of the mass immunization programs, free-riders specifically benefit from the herd immunity created by others who have taken the risks associated with getting immunized. Some have argued that this practice is not unethical or morally wrong, on the basis that free-riding does not necessarily increase the risk to others or threaten the viability of a mass immunization program in any way. So in terms of the consequentialist approach, no specific harm is done. On the other hand non-consequentialist theories posit that free-riding is morally wrong on its own merit. Based on the precepts of virtue ethics, if refusal to vaccinate is based on deeply held personal religious or philosophical beliefs, then one could argue that free-riding is not necessarily immoral. It is important to note in the United States, most states do grant personal belief exemptions from immunization based on religious or philosophical beliefs.

Under what circumstances is parental vaccine refusal not justified and is there any basis for the right of the state to override the parental decision not to vaccinate their child? Based on a number of cases, the United States Supreme Court has upheld the legal and constitutional right of the state (police power) to require and enforce vaccination [16]. In legal terms, the right of the state has been historically established. The constitutional basis of vaccination requirements in the United States is based on the police power of the state [16]. According to

the American Academy of Pediatrics, if the harm from non-immunization is significant, it may constitute an actionable medical neglect on the part of parents [1]. According to the literature [8], if there is a risk for serious and imminent harm to the child from vaccine refusal, the state may override parental refusal. Lyen and Leonard [8] also refer to the issue of distributive justice as a consideration for overriding parental refusal to vaccination. It is also important to consider the fact that the risks and benefit equation may vary over time.

Based on the utilitarianism one could argue that the state can require vaccinations to prevent harm to others who are not immunized [3]. In some cases the exact benefits or risks may not be known, and in this situation one could apply the precautionary principle to justify mass immunization requirements by the state [3]. Because children are considered a vulnerable population one could also apply the precept of weak paternalism to justify mandatory immunization requirements by the state. According to Dawson [2], in some cases the presumption that parents represent the best interests of the child is misconceived, and this justifies overriding the decision by the state. As Dawson [2] observed, "Such a situation arises where there is a substantial risk of significant harm resulting from the decision to either vaccinate or not to vaccinate" (p 189). Dawson [2] in fact went as far as suggesting that in such cases it is not only justified for the state or third party to act, but it is their obligation to act.

Holland [3] evaluated the strong general duty thesis that states that based on moral considerations, there is a general duty for each one of us not to infect others and therefore accept vaccination. The main objection to such an argument is based on the distinction between what are considered acts and omissions. Weak paternalism and libertarian paternalism can also be applied to support the state's right to enforce vaccination mandate.

Lantos et al. [17] argued that personal belief exemptions to the mandate for childhood immunizations should not be allowed. They base their argument on the basis of risk to others who are not immunized for well-founded medical reasons. On the other side of the argument, Opel and Diekema [18] contended that "a just vaccine policy need not prohibit parents from claiming personal belief exemption. We think a more effective approach is one that offers greater flexibility in balancing competing goods and greater opportunity to favorably influence public opinion toward encouraging vaccination. Personal belief exemptions need not be eliminated, just revised" [18].

HEALTHCARE PROVIDERS' ROLE IN ADDRESSING PARENTAL VACCINE REFUSAL

A physician or other primary healthcare provider plays an instrumental role in addressing parental concerns regarding vaccine refusal. At times, family counseling on various concerns may be time consuming, but establishing a trustworthy relationship with parents and their children forms the basis for accurate and nonjudgmental dialogue regarding immunization concerns. Literature supports that even parents with serious concerns about vaccines report their child's healthcare provider as the most important influence and most trusted source for information about vaccines.

CONCLUSION

The answer to the question, “Should parents be allowed to refuse vaccinations for their child?” remains complex and nuanced. In evaluating of all the elements and implications involved in this parental decision, we must consider multiple viewpoints and factors in an attempt to resolve this question. The most plausible conclusion is that the answer will vary and depend on given circumstances at that time. Among the multiple variables to be considered in such an evaluation include disease severity and epidemiology, disease prevalence, the basis of parental reasoning, available information, misinformation, relative risks and benefits of a given vaccine, evolving science, and many others. As this review illustrates, public health ethical principles could be applied to argue for and against parental vaccine refusal for their child.

Chapter 25

FOOD SECURITY, GENDER, AND OCCUPATIONAL SEASONALITY IN URBAN LOW-INCOME HOUSEHOLDS

ABSTRACT

This paper examines an adaptive strategy using occupational choice that can be undertaken by household members especially women in urban poor areas to help ensure their access to food. Our investigation focuses on working women and men in seven predominantly slum communities in North, South, East and West. This study tries examines how women in urban low income households through self-mechanism ensure their households access to food by being employed in some or the other kind of enterprise. This paper attempts to answer following questions: Does concern for household food security influence the choice of women's work in urban low income households? Does seasonality affect the income and skills of women? To answer these questions we analyze the possible relationship between household food security and occupational constraints in slums of Delhi spread across seven clusters. We have used both qualitative and quantitative information from the field interviews. This study takes into account the likely influence of occupational choice of women on gender ascribed roles, seasonality and many more factors which affect the condition of women and adds to their vulnerability status.

Keywords: food security, occupation, seasonality, slums, India

INTRODUCTION

The “State of food insecurity in world” [1] in 2014 presents updated estimate of undernourishment and progress towards Millennium Development Goals and World Food Summit hunger targets. A stock taking of where we stand on reducing hunger and malnutrition shows that progress in hunger reduction at global level and in many countries has continued but substantial effort is needed in many others. The latest estimates indicate that global hunger reduction continues about 805 million people are estimated to be chronically undernourished in 2012–14, down more than 100 million over the last decade, and 209 million lower than in 1990–92 [1]. This shows the poor state of food security over period of years. The “Gender equality and women’s empowerment operational plan, 2013–2020” [2] emphasizes the need for deepening gender mainstreaming and for direct investments in women and girls to close remaining gender gaps and achieve better gender equality outcomes. Another argument put forward in this respect is fully 55% of the gains against hunger in these countries during those 25 years were due to the improvement of women’s situation within society [3]. Another interesting argument put forth is that countries ranking highest on the index of global hunger are also those where such inequalities (gender) are more severe [4].

Recognition of women’s unpaid work in the care economy breaks down the common dichotomy that, while men (or women who join the labor market) produce, women at home consume [5]. The ILO Committee of experts notes that “measures designed to promote harmonization of work and family responsibilities, such as child-care services, should not be specific to women” [6]. The condition for slums are more worst firstly, because the rate at which urbanization is increasing, attracts migrants from the different parts of the countries towards metropolitan areas thus swinging the demand of labour in terms of supply and demand which is leading to more unemployment and underemployment. Secondly, lack of opportunities throughout the year leads to variation in income of women which affects the health status of women and their children. This paper argues that woman through being employed in some or the other form of employment which is even not available throughout the year tries to make their household more food secure and which have positive impact on their health, nutrition and related factors.

METHODS

It may also be noted that the list of ‘jhuggi-jhopdi’ colonies provided in the DDA (Delhi Development Authority) list is neither comprehensive nor exhaustive. Various illegal squatter settlements and marginal settlements located in various parts of the city are not necessarily covered by the list primarily slums have been included in the list. The list of Notified slums was also obtained from the slum wing and notified slums were identified in consultation with experts. A brief description of the sampling procedure used to select the 400 households is given below. In order to select the 400 sample slum households, we have used a two-stage stratified random sampling framework. The basic document we used for our sampling strategy, as mentioned above, is the list of slums called as ‘jhuggi-jhopdi’ clusters (which gives the specific areas where the slums are located) provided by DDA for the year 1994.

This is the latest document available, which lists the number of constituencies, the number of clusters in each constituency, and the number of slums in each cluster. In the first step, we divided Delhi into nine zones on the basis of the geographical location of the 70 constituencies given in the DDA list; thus zones one through seven are respectively, north, north-east, east, south, west, and central Delhi.

Selection of State

The state of Delhi was purposively chosen for the study as it is National Capital Region with large number of slums. Delhi is known for migration of poor people from different states in search of economic opportunities. All these have led to demographic change in Delhi population. Hence, Delhi slums were purposively taken for the study.

Selection of Districts

In the first step, we divided Delhi into seven zones on the basis of the geographical location of the 70 constituencies given in the DDA list; thus zones one through seven are respectively, north, north-east, east, south, west, north-west and central Delhi. Out of seven zones four zones were selected purely on the basis of number of slum in these zones based on the report from MCD list.

Selection of Clusters

As detailed around 400 household has been selected from four Non-notified and three notified slums spread across Delhi in four different directions in order to make the sample more representative. Total of 1997 person were surveyed in all 400 households and to be precise 1,061 persons from Non-notified and 936 from notified were surveyed during the course of the study which includes males, females and children.

RESULTS AND DISCUSSION

Table 1 shows the employment status of women in seven clusters across Delhi but data is restricted only for persons who are aged above fifteen. Under work categories, we can see the number of women who were not working are significantly high around 72.7% while 27.3% of male were also not working. Within all major categories of work women are affected majorly as they are unemployed. Under self-employment category only 16% have taken their own initiative as there is lack of skills and capital among most of the women in slums. There are many reasons for women not being employed apart from the cultural and social reasons. Seasonality appears to be an important factor which affects women's work as work is not available throughout the year which leads to variation in income of the household and directly or indirectly affects their food security status. Women use most of the liquid cash for

purchasing essential items which are required on daily basis such as milk, vegetables oils and many other things if there is significant variation in their income this directly affects their food security. Lack of opportunities make women more susceptible to vulnerability and thus makes households more prone to insecurity in terms of food and many other basics of life.

The gender segregation in terms of occupation is presented in Table 2. It is clear from this that most of the women do not participate in the labour market as they do not have enough skills, training, education and moreover household compulsions, which do not facilitate their entry into the labour market [7]. However, some women out of economic compulsions do participate in the labour market so as to supplement the income of the family which also provides them with food security for their households. It is remarkable to note that though women do not participate in the labour market on full time basis but their mean hours of work were almost similar to those of their counterpart males. An important issue which needs to be discussed here is that women are almost absent from trade, commercial services, transport, security and repairing of machinery activities. However, over the years the state of women occupation has declined significantly, and the most conceivable explanation to this is most of the activities require full time work and travelling which women cannot afford to practise because of household compulsion.

Table 1. Employment status of surveyed households by location and sex above 15 years of age group

Work categories	Slum A		Slum B		Slum C		Slum D		Slum E		Slum F		Slum G		Total

^a Note: This is based on the ILO definition of informal employment and it includes own-account workers and employers employed in their own informal sector enterprises, contributing family workers, employees holding informal jobs, whether employed by formal sector enterprises or informal sector enterprises, or as paid domestic workers, etc.

^b Note: The percentage in this table is row-wise.

^c Note: CL- Casual labour, RW- Regular Wage, SE- Self Employed.

The income-wise gender divide is quite large, the figure shows average income of both the sexes in all categories of work, whereas men income is quite considerably high as compared to female. The construction sector has the highest average earning for both men and women and lowest has been recorded in security for men and personal services for women. It is surprising to note that average income of construction workers for both men and women are significantly high when compared with other occupational groups. This was due to the fact that the construction workers include skilled labour like plumber, carpenter and mason (Raj mistri) who also works overtime this makes his per day income is quite high

when compared with the daily wage labourer. Another reason supporting this argument is that construction activities are on rise in Delhi which enables these workers to find work for most of the time during the year.

Public distribution system (PDS) is an Indian food security system. Established by the Government of India under Ministry of Consumer Affairs, Food, and Public Distribution and managed jointly with state governments in India, it distributes subsidized food and non-food items to India's poor. This scheme was launched in India on June 1997. Major commodities distributed include staple food grains, such as wheat, rice, sugar, and kerosene, through a network of fair price shops (also known as ration shops) established in several states across the country.

Table 2. Occupational category

Occupations	Male	Female	Average Income Rs (Male)	Average Income Rs (Female)	t-test
Professional	26(6.20)	8(8.6)	5050	3229	1.835**

Childs operation	0	1(100)	0	1
For making home at village	0	4(100)	0	4
Marriage	0	1(100)	0	1
Sister marriage	0	4(100)	0	4
Husband operation	0	9(100)	0	9
Total	83(20.9)	131(32.9)	184(46.2)	398(100)

Table 3 and 4 provide the total numbers of below poverty line card holders in the studied slums, where three types of BPL (Below Poverty Line) cards holders were found. These cards are red, yellow and white, where the red card holders get 20 kg of wheat at Rs. 3 per kg, 10 kg rice at Rs. 4 per kg and 5 kg sugar at Rs 14 per kg. But for the yellow and white cardholders the scenario is quite different, where the ration given to these families depends on number of members in the family. The yellow and white cardholders get wheat and rice at Rs. 3 and Rs. 4 per kg per number of persons in the family. While the white card holders also get ration based on the number of persons with exception for sugar and kerosene oil. However, there are lot of problems within the public distribution system (PDS) which leads to black marketing of these food grains as reported by these people.

In the next section we have examined the extent to which households in the urban poor areas are vulnerable to food security. Common measures of food insecurity are based on food expenditures, consumption and household members and nutritional status. These indicators are subject however, to measurement problems as well as conceptual issues [8]. The above figure shows that average expenditure pattern in slums of Delhi. From this we infer that 80% of income is spend on food, expenditure on health is less than 8% and education is even less

than 5%. Income from all sources is so less that the entire money is spends on food. Lack of work both among male and female leads to underemployment and this affect their income as well as food security status of household more decisive.

In order to cope up the seasonality of work during different periods of the year the slum dwellers resort to different kind of strategies or measures which include the use of strategies such as borrowing for food, pawning and selling of assets, reducing food consumption, or just cook once in a day (in bulk) etc. The above table represents the reason for indebtedness among the households, around 32.9% of 400 households were indebted due to one or the other reason while 46.2% of households were not indebted. During the period of survey it was found that most of the households exchanged money among themselves as part of coping strategy in order to run their current expenditure which was short during the particular month.

Skills and knowledge are the driving forces of economic growth and social development for any country. Countries with higher and better levels of skills adjust more effectively to the challenges and opportunities of world of work. Potentially, the target group for skill development comprises all those in the labour force, including those entering the labour market for the first time (12.8 million annually), those employed in the organized sector (26.0 million) and those working in the unorganized sector (433 million) in 2004-05. The current capacity of the skill development programs is 3.1 million. India has set a target of skilling 500 million people by 2022. In terms of skilled labour, that most of the workers both men and women have low basic skills which have significant impact on their wage level. Most of the activities that persist in slums requires low level of basic skills such as truck driver, construction workers, plumber, and hinge (kabja) worker were dominated by men. For women, the major domain of work was part-time, contractual activities that did not require even basic skills and is actually an extension of household activities. This was also the major reason for their wage differentials cross gender. Both the counterparts male (10.26) percent and female (5.4) percent have low levels of skills while around (89.73) percent are employed in non-skilled activities.

Seasonal variation (or seasonality) refers to the degree to which employment rises and falls because of the seasonal pattern (caused by climate and/or institutional events). It governs the extent to which employment estimates must be changed in order to remove the seasonal pattern. In order to address the issues of poverty and food security the seasonal availability of work within low income households has to be addressed so that year round employment can benefit the people at large. Table 7 provides information on different kind of activities prevalent in slums all the year round. It is quite clear from the table that available work opportunities for women is quite minimal as compared to men, further, the labour market was segregated and female participation in the labour market was unremittingly much lower than male participation. Women account for most of unpaid work and when they are paid they face significant wage differentials vis-a-vis their male counterpart. An observation made by Mitra, who has argued that physical segmentation that is seclusion of certain kinds of jobs to certain group of individuals was primarily because of the distance factor within the city and even inexpensive intra-city transport for commutation which does not eliminate these barriers. Women under these circumstances are more ungaurded; they bear major burden of unpaid work which doesn't permit them to travel long distances.

Table 6. Type of skilled labour

Type of Work	Male	Male Income (Avg Income)	Female	Female (Avg Income)	Total
Skilled	43(10.26)	5712	5(5.4)	4833	48(9.3)
Non-skilled	376(89.73)	4500	87(94.56)	2733	463(90.6)
Total	419		92		511

Table 7. Seasonality in work

Month	Activities	Wage /Day	Time/ Day
January, February	Peeling of peas, Making of garlands, removing unused material from zip and jeans, making nut bolt sharper.	1 Dirai=5kg7/dirai 2 Per Garlands, 30 paise/piece 50 paise/piece.	5-6 hrs
			4-5 hrs
			6-8 hrs
			6-8 hrs
March, April	Making of <i>Papads</i> , Taking out stickers from cloth.	20/kg for making <i>papads</i> , 5/piece, 30 paise/piece	6-8 hrs
			5-6 hrs
			5-7 hrs
July, August	No activity	No activity	—
September, October, November	Putting cushion inside vaseline box, removing of unwanted material from finished goods, basket, making of chandeliers (<i>Jumars</i>)	Rs2/bottle, 5Paise /piece, 10/basket, Rs10/piece.	6-8 hrs
			5-6 hrs
			7-8 hrs
			5-6 hrs
Notified Slums			
January, February, March	Packaging of soaps, Refining and Cleansing of copper Making of papads	For 1000 soaps they get Rs 30 Rs 300/day Rs 20/kg	5-6 hrs / day
May, June, July, August	Making of garlands	For one piece they get Rs 1.	4-6 /day

CONCLUSION

Women and girls are affected in two different ways. One is the limits on their access to education and employment opportunities, which curtails their economic autonomy and weakens their bargaining position within the family. Secondly, their weakened bargaining position translates into little or no voice in household decisions, differential feeding and care giving practices favouring boys and men, food and nutrition insecurity, lower health and nutrition outcomes. This paper tries to conclude that women's income makes positive contribution to the household nutritional status. Women in slums do not have regular source of income through being employed in some or other type of enterprise they make significant contribution to their household income and thus making themselves more food secure. This implies that being employed in some kind of enterprise (work as option), and they also make use of other adaptive or coping strategies such as undertaking two or more jobs, which gives them regular source of income. However, it does not allow them to develop their skills in any particular enterprise thus making them more vulnerable. This in turn suggests that there are factors that influence their occupational choice (taking up of two work together) other than food security concern.

Seasonality, was most important factor that affects women work and income quite sharply where certain period no work is available. There are two sets of arguments put

forward in this respect by the slum dwellers, firstly opportunities of work was dependent upon season, and secondly, even within the season the work was not available throughout the year which leads to variation in income which finally makes significant impact on the nutritional status of women and children and household on the whole. Most of the income which is earned from the above said activities is spent on food items. Household with economically dependent adults and larger household were most vulnerable. Thus, women under these circumstances act as catalyst towards household nutrition as most of the surveyed women around 73% spent their income on food, followed by their children education and health. It is also clear through seasonality calendar that during the months of July, August and December there are no activity which can substantiate the income of the women which affect the food security status of the entire household. Improved food intake translates into better health and nutritional outcomes only if accompanied by access to adequate education, health services, water, and sanitation. This paper shows how gender-sensitive policies that empower women within households can contribute to nutritional security.

APPENDIX

Occupational Groups

Professional: Auxiliary Nurse Midwife, accredited Social Health Activist, lady Health Visitor, anganwadi Worker and Helper, supervisor, computer operator, NGO worker, registered medical practitioner, engaged in field work (as assistants), teacher, tutor (home based who are in their graduation), doctors.

Sales: Fruit seller, vegetable seller, baas ki tokri maker and seller, toy seller, kachori seller, small peddlars and hawkers (Peddlars are mainly associated with Food products), seller of food products (Kiranewala), acid and phenyl Seller.

Trade: Butcher, fish seller, worker in hotel, worker in community centre, worker in private tent firm, assistant in shop, tea shop owner/worker, milkman, petty traders, contractors.

Personal services: Barber, cobbler, cook, domestic labour (engaged in cleaning), bathroom cleaner, domestic maid, helper in house (for keeping the child), clothes washer, ironing clothes, Roti maker.

Manufacturing: Workers involved in utensils (barthan maker and polishing it with acid), confectioner, cover maker, dial maker, metal processor, worker in workshop, skilled labour, peeling of peas, making of garlands, removing unused material from zip and jeans, making nut bolt sharper, making of Papads, taking out stickers from cloth. putting cushion inside vaseline box, removing of unwanted material from finished goods, basket, making of chandeliers (Jumars).

Commercial services: DJ operator, drum player, MCD worker, musician, peon, worker in office (like sweeper, multitasker, attendant, etc.).

Transport: Auto driver, taxi driver, cab operator, rickshaw puller, conductor, ticket checker.

Construction: Construction labour, carpenter, marble cutter, painter, Raj Mistri, sanitary worker.

Security: Security guard in private hospital, constable, homeguard, security guard in private enterprise.

Chapter 26

TRADITIONAL HEALTH CARE PRACTICES OF WOMEN IN URBAN SLUMS: FOCUS ON MATERNAL HEALTH AND NUTRITIONAL STATUS

***Shradhanvita Singh*, PhD, Nehal A. Farooquee, PhD
and Bikram K. Pattanaik, PhD***

School of Liberal Arts, Noida International University and School of Extension and
Development Studies, Indira Gandhi National Open University,
Delhi, India

ABSTRACT

This study examines the health, nutritional status, and health care seeking behaviour of a community based sample of 400 postpartum women from an urban slum in Delhi, India. It describes physically impoverished environment, where malnutrition is serious, and non-trivial morbid episodes as a consequence of childbirth are very common. Malnutrition was found to be widespread among women residing in slums. During the first few weeks postpartum over three-quarters of the women reported non-trivial illness. The frequency of reported illnesses was significantly associated with both increasing age and parity. As severe poverty persisted, most of the women reported complications (63.5%) and received some form of health care from a wide range of medical practices and traditional health care providers, with traditional birth attendants (TBAs) and unqualified medical care providers being the most frequently utilised. This study highlights the plight of these women in a precarious environment and showed how their health was compromised by cultural and political constraints. We conclude that while the burden of postpartum morbidity is very high, the incorporation of traditional practitioners and unqualified western care providers into maternal health training programs, together with efforts to empower women, could be effective in improving the health status of mothers in this marginalised and fragmented community. To achieve this outcome, a clearly articulated and integrated approach to development in slum communities is required.

INTRODUCTION

Maternal health refers to the health of women during pregnancy, childbirth and the postpartum period. While motherhood is often a positive and fulfilling experience, for too many women it is associated with suffering, ill-health and even death. The “State of the world’s mothers” 2015 focuses on vulnerable group of mothers and children mainly from low income group in urban areas and it highlights the key causes for mortality in Sub-Saharan Africa and South Asia [1].

Bhutta et al. [2] argued for strategies to promote complementary feeding with or without provision of food supplements, micronutrients intervention, general measures to improve recurrence of diseases and thus improving overall health status of the people. On the other hand Gupta [3] argued that in the majority of cases there was a lack of knowledge and correct practices regarding newborn care among mothers, which should be promoted through improved coverage with existing health scheme. Ghosh and Sharma [4] suggested that better antenatal care, safer delivery practices and post-natal visits observed among women resulted in less morbidity and mortality. Another remarkable argument forwarded by Paula and Stephenson [5] asserted that poor quality of service offered at government institutions was a motivating factor for delivery at home. On a similar note Parashar [6] found that inadequate knowledge and adverse practices regarding neonatal care among mothers was revealed in the study area, while Iyengar [7] argued that the quality of services administered was adequately addressed.

Even though much work has been done on health issues, there is still a paucity of data on the kind of complications and morbidity pattern among low income households. Sundar and Sharma [8] in their paper examined the pattern of morbidity and healthcare utilization by urban poor living in slums and resettlement colonies of Delhi and Chennai. The findings of their study suggested that women were at an added risk. Lack of awareness about hygiene, low levels of education, low social status, and stigma about gynecological problems may have resulted in higher actual morbidity and lower utilization of health care. Izugbara [9] also argued that in many developing countries like for example Nigeria maternal reproductive health has long been recognized as a most urgent public health and social policy priority. Krishnaraj and Chanana [10] argued that female education plays a major role in determining health, particularly that of their children. Fronczak [11] in their paper described associations among delivery-location, training of birth attendants, birthing practices, and early postpartum morbidity in women in slum areas of Dhaka, Bangladesh. Associations among maternal characteristics, birth practices, delivery-location, and early postpartum morbidity were specifically explored. Self-reported postpartum morbidity was associated with maternal characteristics, delivery-related complications, and some birthing practices. Dais (a term used for untrained traditional birth attendants in rural and urban slum areas) with more experience were more likely to use potentially-harmful birthing practices, which increased the risk of postpartum morbidity among women with births at home. Postpartum morbidity did not differ by birth-location. Safe motherhood programmes must develop effective strategies to

discourage potentially-harmful home-based delivery practices demonstrated to contribute to morbidity.

Khan et al. [12] argued that pregnant women inhabiting urban slums were a “high risk” group with limited access to health facilities. The study examined whether hazardous maternal care practices existed and whether there were differences in the utilization rates of health services in two different slums.

The current paper aims to highlight the maternal health status of women in slums of Delhi, which includes antenatal care access, child birth practices, and complications during pregnancy and morbidity pattern among the women during their last delivery.

METHODS

A descriptive research design was used in this study in order to meet the objectives and justify the hypothesis. The study employed both quantitative as well as the qualitative methods. Descriptive research included surveys and fact-finding enquiries of different kinds. The major purpose of descriptive research is description of the state of affairs as it exists at present. There are three ways a researcher can go about doing a descriptive research.

- Observational, defined as a method of viewing and recording the participants Case study, defined as an in-depth study of an individual or group of individuals.
- Survey, defined as a brief interview or discussion with an individual about a specific topic.

Thus, in order to see interlinkages between health, work and education the above design was considered most suitable.

Sampling Procedure

The state of Delhi was purposively chosen for the study as it is national capital region with a large number of slums. As a first step, we divided Delhi into seven zones on the basis of the geographical location of the 70 constituencies given in the DDA (The Delhi Development Authority was created in 1955 under the provisions of the Delhi Development Act to promote and secure the development of Delhi) list; thus zones one through seven are respectively, north, north-east, east, south, west, north-west and central Delhi. Out of seven zones four zones were selected purely on the basis of the number of slum in these zones based on the report from the *Municipal Corporation of Delhi (MCD)*.

Selection of Clusters

A “non-notified slum” is a compact urban area with a collection of poorly built tenements, mostly of temporary nature, crowded together usually with inadequate sanitary and drinking water facilities in unhygienic conditions, if at least 20 households lived in that

area. Urban areas notified as slums by respective municipalities, corporations, local bodies or development authorities were treated as “notified slums”. A total of 400 household has been selected from both non-notified and notified slums spread across Delhi. 1,997 persons were surveyed in a total of 400 households. Thus, 1,061 persons from non-notified and 936 from notified were surveyed during the course of the study, which includes males, females and children.

RESULTS AND DISCUSSION

Gravida indicates the number of times the woman has been pregnant, regardless of whether these pregnancies were carried to term or not. A current pregnancy, if any, is included in this count. The section below focuses on health status of women which covers antenatal care, health complications among women, morbidity pattern among women, complications during postpartum period. The second section focuses on intrapartum morbidities and birth practices in slums of Delhi and the last section focuses on the postpartum problem and nutritional status of females in slums.

Table 1 provides information on gravida of women in urban slums of Delhi. The term gravida can be used to refer to a pregnant woman. A “nullgravida” is a woman who has never been pregnant, a “primigravida” is a woman who is pregnant for the first time or has been pregnant one time, a “multigravida” or “secundogravida” is a woman who has been pregnant more than one time. From the table it is very clear that women in slums marry at a very early age. Most women conceive in their early adulthood. Out of 155 women in the 20-29 year age group category, 27.1% completed their third pregnancy. Out of 139 women in the 30-39 year age group, 23.7% completed their fourth pregnancy, which means that women in slums conceive at a very early age and the parity between the children is very short. Lack of spacing between the children also results in poor maternal health status of women in slums of Delhi.

Antenatal Care

Prenatal care is preventive healthcare with the goal of providing regular check-ups that allow physicians, nurses or midwives to treat and prevent potential health problems throughout the course of the pregnancy, while promoting healthy lifestyles that will benefit both mother and child.

The World Health Organization defines antenatal care as recording medical history, assessment of individual needs, advice and guidance on pregnancy and delivery, screening tests, education on self-care during pregnancy, identification of condition detrimental to health during pregnancy, first time management and referral services. Table 2 shows the pattern of antenatal care utilisation for their last child birth among urban slum dwellers. Respondents interviewed among eight slum clusters from all around Delhi displayed a very small proportion of women that had received full antenatal care services during their last pregnancy. Similarly, out of 400 women interviewed only 75 women responded, when asked about antenatal care services. Out of 75 women only 69.3% had measured their weight during the last pregnancy, while 24% who made partial visits to facility had measured their weight

and 6.7% did not pay even a single visit to a facility. Similarly, out of 79 women only 59.5% who had received full antenatal care services. While 15.2% of women got their hemoglobin measured and 25.3% did not make even a single visit to the facility. The major reason for not accessing ANC (antenatal care services) during their last pregnancy was lack of knowledge and education (40%) followed by mother in law who did not allow (20%). However, 20% did not consider it mandatory and only 12% responded socio-economic condition to be a major factor.

Table 3 provides information on various types of complications reported during their last pregnancy. Complications such as night blindness, blurred vision, swelling on legs and face, excessive fatigue and anemia together amounted to 52.3%. Nonetheless, women in very small percentage reported problems like anemia (8.5%), oligohydramnios (0.5%), urine infection (0.5%), infection in uterus (0.5%), problem in stomach (0.5%), pain in abdomen (5%), body swollen (4.5%), pain in legs (1%), low blood pressure (2.5%) and jaundice (0.5%). Around 58.5% of women in notified slums (these slums are recognized/ registered by their respective municipalities) faced any complication during their last pregnancy, as compared to 14.5% in non-notified slums (these slums are not recognized /registered with their respective municipalities).

Table 1. Age group with pregnancy status of the women

Age Group	Number of Children						Total
	1	2	3	4	5+	No Children	
15-19	7(100)	0(0)	0(0)	0(0)	0(0)	0(0)	7(1.75)

Total	204		83	287

113 women did not made any OPD visit in 3 months preceding the survey.

Note: Figure in the parenthesis shows percentage to their respective total.

Antenatal Morbidities among Women

Table 4 shows various types of communicable and non-communicable diseases prevalent among women in slums three months preceding to the survey. Out of 400 respondents, 113 (28.25%) did not make any OPD (outpatient department it means a person is not admitted in hospital he/she just makes a visit for consulting a doctor) visit within three months preceding the survey. From the table it is evident that 65% of women suffered from jaundice,

pneumonia (10%), malaria (1%), tuberculosis (4%) cough and cold (12%), gastroenteritis (1%), dengue (3%), typhoid (2%) and diarrheal problem (1%). However, women suffered more from non-communicable diseases, as to communicable diseases. Problem such as kidney disorder and respiratory distress makes up around 51% of non-communicable diseases. The major reason for spreading of communicable diseases in these low income households is because of the poor quality of water supply they have been receiving, which makes them prone to water borne diseases. Besides, lack of maintenance of proper sanitation and hygiene further adds to the agony of these low income settlements.

Intrapartum Morbidities and Practices during Child Birth

In obstetrics, the period from the onset of labor to the end of the third stage of labor is called the intrapartum period. In India, maternal mortality is estimated at 540 per 100,000 live births [13]. The intrapartum period, although a limited time span, is of critical importance, as at this stage a seemingly normal labour can suddenly degenerate into a crisis.

Among women with deliveries at home, self-reported postpartum morbidity was significantly associated with risk parity (primiparity or grand-multiparity of five or more births), poorest economic strata, under nutrition, anemia, meeting operational definitions for delivery-related complications, and malposition of the infant (see Table 6). With regard to delivery practices, postpartum morbidity was significantly associated with having two or more vaginal examinations and reports of practices to expel the placenta or stop bleeding (forced gagging, applying hard manual pressure to the abdomen or pulling on the umbilical cord). Table 7 shows various kinds of practices which were prevalent during birth in slums at home. These practices are quite hazardous, which often results in morbidity or mortality either in children or mother. During the survey period many women said that after delivery they were immediately transferred to the hospital as emergency cases for excessive bleeding as one of the major problem after delivery.

Table 7 provides information on various kinds of problems reported by women during postpartum period in low income settlements. The majority of women reported complication such as excessive blood clots, foul smelling discharge and pain in lower abdomen as major complications during the postpartum period. The major reason for these complications are the lack of any antenatal visits before delivery (see Table 2).

Table 5. Problems during intrapartum period

Intrapartum Problems	Given Tea	Given Hot Milk	Nothing Given	Total
No problem	36(85.7)	4(9.5)	2(4.8)	42
Inadequate labour pain	5(2.6)	136(69.4)	55(28.1)	196
Prolonged labour	2(1.5)	27(20.5)	103(78)	132
Heavy bleeding during labour	4(16)	14(56)	7(28)	25
Loss of consciousness	1(50)	0	1(50)	2
Heavy bleeding after labour	0	3(100)	0	3
Total	48(12.1)	184(45.7)	168(42.2)	400

Table 6. Delivery practices

Delivery Practices	Categories	Number	Share (%)	Medical Practices
Cleaning of the floor prior to delivery	Yes	96	23.8	Yes
Washed hands with disinfectants	Yes	88	22	Yes
Boiled instruments used for cutting cord	Yes	92	23	Yes
Boiled the thread for tying umbilical cord	Yes	101	25.25	Yes and use of clamp
Wore gloves	Yes	43	10.75	Yes
Given hot milk and egg during delivery	Yes	237	59.25	
Posture during delivery	Squatting	213	53.25	Supine
	Supine	187	46.75

Total	200	200	400

Note: Figure in the parenthesis shows percentage to their respective total.

Table 8 shows cross-classification of nutritional status of women with respect to various age groups. However, with increase in age most of the women surveyed faced problems of inadequate calorie intake. Around 11.7% of women within different age group were found to be underweight, while around 7% of women within different age group were severely underweight. Many of the women suffered deficiency in necessary vitamins and micronutrients found in fruits, vegetables, and dairy products. During the course of the survey it was found that many families in slums do not have access to pulses, green leafy vegetables

and dairy products. During the past few years, due to consistent rise in the prices of milk, vegetables and pulses, many slum dwellers are unable to get these products. Women who consume milk or curd everyday are less likely than other women to have CED (chronic energy deficiency). Similarly, women who consume fruits or chicken, meat or fish on a daily basis are less likely than other women to have CED. Apart from CED, a significant proportion of women suffers from overweight and obese, which clearly indicate that this problem cannot be ignored. This phenomenon is becoming a well-recognized aspect of nutrition transition, with change in dietary pattern and levels of physical activity leading to increase in overweight.

Table 8. Nutritional status of women analyzing body mass index (N = 382)

Age categorical	Less than 15 (very severely underweight)	15-16 (severely underweight)	16-18.5 (underweight)	18.5-25 (normal)	25-30 (overweight)	30-35 (moderate obese)	35-40 (severe obese)	Total
15-19	0	0	0	4 (66.6)	2 (33.3)	0	0	6 (100)
20-29	7 (4.09)	4 (2.33)	22 (12.86)	83 (48.50)	43 (25.14)	12 (7.07)	0	171 (100)

Note: Figure in the parenthesis shows percentage to their respective total.

CONCLUSION

This study demonstrated that the health of women in slums was very poor, as an outcome of severe economic, environmental and social deprivation. In addition, housing, sanitation and health services are grossly inadequate. Low status is reflected in high levels of malnutrition, as shown in low body mass indices. Further, the women reported significant morbidity following child-birth. The data gathered from this urban slum in Delhi were consistent with the relatively scarce information available on comparable populations in Delhi. Perhaps surprisingly, given the poverty of these people, there is a wide range of untrained medical practices and traditional practitioners who ply their services to the slum dwellers and the respondents used their services fairly frequently. These women and their families clearly consider health care services to be desirable, and prove this by voting with their feet and using their meagre resources to do so.

Not only do these slum dwelling women live in appalling physical conditions, but they also suffer high rates of illiteracy and have little decision making power, which serves to reinforce their inferior status. Furthermore, they are often denied the support of an extended social network due to the highly fragmented and mobile nature of the population. It is clear that the low status of women in Delhi in general, and in slum communities in particular, is a severe impediment to bringing about improvements in their overall health. Any attempts to improve the status of these women must take as a starting point an in-depth understanding of

their particular circumstances. Such an understanding may reveal, as this study has, that in spite of everything, women are surprisingly active in pursuing health care services, particularly those they could access within the bustee or slums. It is this positive motivation which should be mobilised in any community-based initiatives.

Long-term programs aimed at improving women's status, education and employment must be part of an integrated program for development in slum communities. We consider such initiatives need to go hand in hand with comprehensive community based health care services that reach out to women within the slums, rather than services that wait for powerless women to come to them. This study also offers some practical scope for potential improvement.

In short, we would recommend that the growing problem of urban slum health needs urgent attention, and that the primary health care approach, emphasising basic and accessible low-level services linked to, and supported by, the community, holds the best hope for improvement. It is clear that this group of poor urban mothers is at a very high risk, and should be recognised as such and targeted by health planners and policy makers. Clearly, overall economic improvement is fundamental, and policies should be directed to documenting and improving the living conditions of the urban poor, perhaps especially those in the present group, who are an impoverished sub-group within the deprived underclass. This study has contributed to the scant information we have on health problems and their management among mothers living in the urban slums of Delhi.

ABSTRACT

Mainstream Chinese cultural values have their roots in Confucian, Taoist, and Buddhist teachings that have been transmitted through generations. This study examines Chinese beliefs about adversity and their association with treatment fears among young psychotropic substance abusers undergoing residential drug treatment in Hong Kong. Results showed that young substance abusers' levels of current treatment fears and anticipated discharge fears were negatively correlated with the Chinese Cultural Beliefs about Adversity Scale. The findings imply that young substance abusers under treatment who have a stronger endorsement of positive Chinese cultural beliefs about adversity are expected to have a lower level of anticipated discharge fears. The role of Chinese beliefs about adversity in the treatment of young substance abusers is discussed.

Keywords: Chinese beliefs about adversity, treatment fears, young substance abusers, residential drug treatment, Hong Kong

INTRODUCTION

According to the statistics of the Central Registry of Drug Abuse (CRDA) maintained by the Government of the Hong Kong Special Administrative Region (2015), the average age for reported adult drug abusers was 38 years, and the mean age for first use of drugs was 18 years. For the drug abusers under 21 years, the average age was 18 years, and the mean age for first abuse was 15 years. Most of them (87.8%) were psychotropic substance abusers. The most commonly abused drugs reported by young substance abusers were methamphetamine (40.9%), ketamine (36.7%), and cocaine (29.2%).

The CRDA statistics (2015) showed that about half of the current drug abusers reported that their main reason for drug use was relief of boredom, depression, or stress [1]. These findings echoed the findings of Shiffman and Wills [2] who found that coping ability of an individual in handling stress and temptation was a determinant of substance abuse. Research studies suggested that youngsters tended to use drugs as a coping strategy when they wanted to evade encountering their problems and negative emotions [3-5]. Echoing the results of the above studies, Aebi et al. [6] reported associations among avoidant coping pattern, psychosocial adversities, and substance use. Their findings showed that adolescents who frequently showed avoidant coping would have lower ability to deal with their psychosocial adversities, such as family violence, imprisonment of a family member, financial problems, school failure, and sexual abuse, which subsequently predicted their substance use behaviour. In addition, Shek [7] found that a lower level of endorsement of Chinese cultural beliefs about adversity was associated with a higher level of substance abuse.

With specific reference to the Chinese culture, Confucian, Taoist, and Buddhist teachings form the main roots of Chinese cultural values. These traditional values and rules that passed down through generations tend to govern the behaviour of individuals [8]. Besides, the ways that Chinese cope with adverse life events can be explained by the cultural values and attitudes that have been transmitted down through the generations. According to Shek [9], Chinese cultural beliefs about adversity include those concepts about the nature of adversity such as its causes, consequences and the proper coping behaviour.

Life adversity in Confucian teaching can be interpreted as fate. According to Xunzi, people should not challenge or change their fate. Life adversity is pre-assigned and should be regarded as an opportunity in life. People should seize adverse situations as a chance for personal development and subsequently overcome the hardship in life [10]. Similar to the Confucian teaching, Taoism also regards adversity as part of the life path of an individual. People are advised to accept it with endurance and a peaceful mind, trying to embrace it as a learning process. In Buddhist teaching, adverse events are regarded as karma, which refers to a consequence driven by the intent of the action. It can be viewed as a retribution or transmigration that people should accept. In summary, Chinese cultural beliefs about adversity accept that adversity is inevitable. However, people are encouraged to adopt an optimistic and positive attitude rather than taking it as a suffering. They can seize it as an opportunity for personal development and a chance to succeed. For people who admit that adversity is retribution, they can rebound from the situation when they commit to doing more benevolent acts to compensate for their bad deeds. As such, people will demonstrate their strong capacity for enduring frustration and encouraging themselves to rebound from adverse situations. This could positively inspire or enlighten people to deal with their adversities

positively and to maintain good mental health. On the contrary, people will view adversity as suffering or a failure if they adopt a negative attitude towards adversity.

Every society has its own unique cultural value system for raising its children. Masten [11] pointed out that special cultural customs, beliefs and values can become protective factors for individuals facing adversity. Even though today's social environment is rather complicated, and children's exposure to adversity is not the same, traditional wisdom provides a sound framework for individuals in responding to social environments and dealings with others. Likewise, Chinese people also have cultural beliefs about adversity, which serve as protective factors for Chinese people to overcome life adversities. Research findings suggest that people who identified with more positive Chinese cultural beliefs about adversity (such as "where there is a will, there is a way") have a stronger sense of mastery in life and adapt easier to their environment [12]. People may become more resilient to cope with stress when they can work through hardship and gain benefits through exposure to difficulties [13, 14]. On the contrary, people may have more fears when their life adversities are not properly dealt with. They may turn to other coping options (such as substance use) to alleviate their emotional distress arising from the adversity.

Based on the above background, we asked the following research question in this study - is there any relationship between Chinese beliefs about adversity and treatment fears? Consistent with the existing literature, it was hypothesized that there would be a negative relationship between Chinese beliefs about adversity and treatment fears among young psychotropic substance abusers undergoing residential drug treatment (Hypothesis 1). Besides, it was hypothesized that the level of endorsing Chinese beliefs about adversity would be negatively related to anticipated treatment fears amongst young substance abusers undergoing residential treatment (Hypothesis 2).

METHODS

To explore the relationship between Chinese beliefs about adversity and treatment fears, a cross-sectional study was designed to collect information from young psychotropic substance abusers undergoing residential drug treatment in Hong Kong. As a result, 303 participants were recruited from various residential drug treatment centers by means of convenience sampling.

The age of these 303 participants ranged from 14 to 25 years with a mean age of 20.03 (SD = 2.9). Their age of first drug use ranged from 9 to 24 years with a mean age of 14.71 (SD = 2.09). About 82.8% of them had been poly-drug users at the time they admitted to residential drug treatment. The most popular drugs among the participants were ketamine (83.2%), cocaine (63.0%), cannabis (45.5%), methamphetamines (39.9%), and nimetazepam (37.3%). About 40% of them had an educational attainment of above Secondary 3 (equivalent to Grade 9 in the US). The majority of the participants were Chinese (96%). Most of the participants (83.7%) were recommended by forensic orders (probation order, superintendent's discretion scheme, supervision order, or bound over) to receive residential drug treatment. About 16% of the participants stated that they chose residential drug treatment reluctantly. 20 participants (6.6%) were diagnosed with mental disorders at the same time. The participants

had undergone an average of 9.08 months of drug treatment at a residential drug treatment agency, with a range from 2 weeks to 8.5 years ($SD = 13.5$ months).

The data in this study were collected within a time span of 13 months from June 2011 to July 2012. The objectives of the research, procedures of data collection, and the use of the data so collected were explained to the participants. In addition, the participants were informed of their rights to participate on a voluntary basis and to withdraw from the study at their free will. After obtaining their consent, the participants were invited to self-administer a questionnaire. Ample time was given to the participants to answer the questionnaire which took them roughly 45 to 60 minutes to complete.

Instruments

The 35-item Early Treatment Fears Scale was developed and validated in this study to measure the fear level of young psychotropic substance abusers arising from different causes in their early treatment phase when they underwent residential drug treatment. The scale was developed mainly by reviewing the literature on substance abuse, generating qualitative data from the focus group interviews with young substance abusers and experienced social workers in the drug field, as well as using the clinical experience of the first author [15]. The overall reliability analysis with Cronbach's alpha showed that the Early Treatment Fears Scale (ETF) was reliable ($\alpha = .93$), showing good internal consistency. The Early Treatment Fears Scale (ETF) and its subscales showed good item-total correlations, reliability, validity, and dimensionality in measuring early treatment fears of young psychotropic substance abusers in a Chinese context.

Anticipated Discharge Fears Scale (ADF)

The 39-item Anticipated Discharge Fears Scale was developed and validated in this study to measure the treatment fears of the young psychotropic substance abusers who were about to be discharged from residential drug treatment programs. The scale was formulated from reviewing of substance abuse research [15], qualitative data generating from focus group interviews with young substance abusers and experienced social workers in the drug field, as well as the clinical experience of the first author. The overall reliability analysis with Cronbach's alpha showed that the Anticipated Discharge Fears Scale (ADF) was reliable ($\alpha = .94$), showing good internal consistency. In addition, the ADF and its subscales showed good item-total correlations, reliability, validity and dimensionality in measuring anticipated discharge fears of young psychotropic substance abusers in the Chinese context.

The Chinese Beliefs about Adversity Scale (CBA)

The 9-item Chinese Beliefs about Adversity Scale (CBA) focusing on Chinese beliefs about adversity was developed by a group of psychologists and social workers in this study. For each item, respondents were requested to indicate their degree of agreement with the item

on a 6-point Likert scale ranging from strongly disagree to strongly agree. Adequate reliability of this scale was reported [7, 9]. There are 9 items under this scale, namely, (1) “hardship increases stature”; (2) “whether a life is good or bad depends on fate”; (3) “where there is a will, there is a way”; (4) “if you work hard enough, you can turn an iron rod into a needle through grinding”; (5) “poverty stifles ambition”; (6) “diligence is an important factor to overcome poverty”; (7) “man is the master of his own fate”; (8) “a contented person is always happy”; and (9) “man is not born to greatness, he achieves it by his own effort.” In this scale, item 2 and item 5 are negative cultural beliefs about adversity, while the rest of the items are positive items about adversity.

RESULTS

Results showed that participants’ endorsement of the Chinese beliefs about adversity were significantly related to their level of early treatment fears ($r = -.105$, $p < .05$, one-tailed test), thus supporting Hypothesis 1. In addition, the findings also showed that participants’ level of early treatment fears was negatively correlated with the negative Chinese Cultural Beliefs about Adversity Scale ($r = -.097$, $p < .05$, one-tailed test), suggesting that the strong endorsement of participants on negative Chinese cultural beliefs about adversity with a higher level of early treatment fears.

Besides, participants’ level of anticipated discharge fears was negatively correlated with the Chinese Cultural Beliefs about Adversity Scale ($r = -.130$, $p < .05$, two-tailed test), giving support to Hypothesis 2. In addition, the findings also showed that participants’ level of anticipated discharge fears was negatively correlated with the negative Chinese Cultural Beliefs about Adversity Scale ($r = -.204$, $p < .001$, two-tailed test), implying that the strong endorsement of participants on negative Chinese cultural beliefs about adversity with a higher level of anticipated discharge fears (see Table 1).

Table 1. Correlations among Early Treatment Fears Scale, Anticipated Discharge Fears Scale, and Chinese Beliefs about Adversity Scale and their Subscales

	CBA	Positive CBA	Negative CBA
ETF	-.105a	-.067	-.097a
ADF	-.130*	-.042	-.204**

** Significant at the 0.01 level (2-tailed).

* Significant at the 0.05 level (2-tailed).

^a Significant at the 0.05 level (one-tailed).

Note: ETF = Early Treatment Fears Scale;

ADF = Anticipated Discharge Fears Scale,

CBA = Chinese Beliefs about Adversity Scale;

Positive CBA = Positive Chinese Beliefs about Adversity;

Negative CBA= Negative Chinese Beliefs about Adversity.

DISCUSSION

Generating a representative sample of illicit drug users for substance abuse research can be challenging because there is no sampling frame. According to Hendricks and Blanken

[16], a random sampling methodology with a drug-using population is impossible for three reasons: potential legal and social sanctions; inability to estimate sample size from an accurate sampling frame; and hidden nature of the drug use population. In response to this research barrier, the use of service-based samples (convenience sampling) of young psychotropic substance abusers undergoing drug treatment at non-government residential treatment institutes to collect data did help solve the data collection problem, and it provided a means to gather information from this population group.

Consistent with our hypothesis, this study showed that the young substance abusers' total scores of endorsement of Chinese cultural beliefs about adversity were significantly related to their level of early treatment fears. Besides, their endorsement of Chinese cultural beliefs about adversity was negatively correlated with their anticipated discharge fears.

The findings underscore the importance of cultural beliefs in influencing the adjustment and well-being of substance abusers. Some deep-rooted values for adversity in the Chinese culture inherited for generations like "hardship increases stature," "one must be testified by sustaining hardship in the way of success" gave positive influences to young substance abusers in facing their treatment fears. The cultural beliefs encourage people to overcome stress associated with negative emotions and to provide a cognitive structure that gives a sense of control over life [9, 19]. Under proper counselling, young substance abusers will understand that both physical and mental discomforts arising from drug treatment can be alleviated gradually. Programs designed with integrated traditional Chinese beliefs about adversity can surely help much in this area, in particular, in the development of resilience. Owing to the lack of research study about the relationship of Chinese beliefs about adversity and treatment fears of young substance abusers in the Western and local context, the present findings can be regarded as pioneering in nature. It is suggested that similar attempts should be carried out to examine this issue in western contexts.

Practically, the use of the indigenous Chinese Cultural Beliefs about Adversity Scale in this study helped illuminate how young psychotropic substance abusers perceive adversity and the relationship of those perceptions with treatment fears. Service practitioners may include cultural beliefs about adversity in the intervention process by adopting a cognitive orientation to change clients' beliefs and thinking. For instance, they can help clients maintain positive thinking when they encounter adversity. It would also be worthwhile to identify subcultural beliefs about adversity in different Chinese societies and to investigate the relationships between such beliefs and the factors affecting the relapse of young substance abusers. The program can include service learning program like serving poor children, so that young substance abusers can enhance their awareness of developing positive thinking in encountering adversity.

Of course, it is noteworthy that a cross-sectional design was adopted in this study. Obviously, cross-sectional data always limits certainty on the direction of causality between variables. Hence, researchers should collect longitudinal data using large samples in the future to illuminate the relationship between cultural beliefs about adversity and treatment fears among young substance abusers.

ACKNOWLEDGMENT

ABSTRACT

Based on two samples of Hong Kong Chinese adolescents, the psychometric properties of a scale assessing adolescent perceptions of non-conflict related attributes in the marital life of their parents were examined. Results from both samples showed that the scale possessed good internal consistency, test-retest reliability, criteria-related validity and convergent validity. For the dimensionality of the measure, results suggested that there was one factor of the scale. The present study is a pioneer attempt to examine the psychometric properties of a scale assessing perceived non-conflict related attributes in parental marital relationship amongst Chinese adolescents.

INTRODUCTION

Inter-parental relationship affects adolescent development and mental health in many ways [1, 2]. For instance, a high level of inter-parental conflict and overt inter-parental violence are risk factors for both depression and aggression in adolescents [3, 4]. Besides, inter-parental conflict was related to adolescent internalizing and externalizing disorders, conduct problems, poor peer interaction, poor health, depression, anxiety, attachment insecurity, and low self-esteem [1, 5, 6-11].

In addition to conflict-related attributes, there are studies showing that non-conflict related attributes of inter-parental relationship, such as the degree of care and concern, also influenced adolescent development. Unfortunately, compared with inter-parental conflict, non-conflict related attributes received less research attention. Lack of studies and assessment tools on non-conflict related attributes is particularly obvious for non-conflict related aspects of perceived marital quality from the perspective of adolescent children (i.e., inter-parental relationship perceived by adolescents).

Developing assessment tools for adolescents' perceptions of inter-parental non-conflict related attributes is important for three reasons. First, as the concept and the theories related to non-conflict-related attributes are under-developed, a validated measurement tool would facilitate empirical studies in this area, which would make theorization and conceptualisation of the related concepts and theories possible. Second, inter-parental non-conflict related attributes might be particularly important for Chinese people because relationship harmony is strongly emphasized in the Chinese culture [12]. As conflict behavior is not easily expressed in Chinese families (thus its occurrence may be low), inter-parental conflict may not be a sensitive indicator of inter-parental marital quality perceived by children [12]. Therefore, to understand inter-parental relationship perceived by adolescent children, development of assessment tools for adolescents' perceptions of inter-parental non-conflict-related attributes is necessary. Third, assessment tool in this area helps researchers understand how family relationship impacts adolescents in Chinese society. This would help the development of indigenous Chinese family concepts which would enhance our understanding of Chinese families and construction of relevant family models [13, 14].

The purpose of the paper was to report two studies on the psychometric properties of a scale assessing perceived inter-parental non-conflict related attributes among adolescents in Hong Kong. The scale was developed based on a literature review of marital quality and measurement tools of marital relationships and interactions [15-17]. Furthermore, two focus groups of adolescents and two focus groups of social workers with family services experiences were interviewed separately to understand adolescents' views on inter-parental relationships and interaction qualities. Based on both literature review and focus groups findings, 60 items were generated and were categorized in terms of twelve themes, including Togetherness, Communication, Appreciation, Criticism, Concern, Helping, Understanding and Acceptance, Trust, Satisfaction, Indigenous Chinese concepts, Passion, and Commitment.

Before the scale can be objectively used in research and practice contexts, it is important to establish the psychometric properties of the scale. In the context of assessment, researchers commonly examine three psychometric properties of a scale. First, reliability of the measure, such as internal consistency and test-retest reliability, should be assessed. Second, validity of the scale, such as criterion-related validity and convergent validity, should be explored. Finally, the dimensions of a measure (i.e., factorial validity) should be examined. In this paper, data were collected from two adolescent samples to evaluate these psychometric properties of the measures.

METHODS

Study 1 was based on a small convenience sample of adolescents aged 12 to 16 years. Adolescents with intact (i.e., a family in which parents remain married) and non-intact family (i.e., a family in which parents are divorced or separated) were recruited in a school social work service unit of a non-governmental organization. Altogether 23 male and 24 female adolescents were recruited from the school social work service unit. Their average age was 14.45 (SD = 1.30; Min = 12; Max = 16), with 28 of them coming from intact families while 19 of them were from non-intact families.

Instruments

Participants were requested to fill in a scale assessing adolescents' perception of inter-parental non-conflict related attributes and some basic demographic information.

Data Collection and Data Analysis Plan

Invitation letters of Study 1 were sent to adolescents' parents through the school social work unit. The objective of the study was explained and confidentiality of the data was emphasized in the letter. After obtaining written parental consent and adolescents' own consent, participants were asked to fill in a scale assessing adolescents' perception of inter-parental non-conflict related attributes on a 6-point scale, ranging from never [1] to always [6]. They were also asked to report basic demographic information including gender and age.

To assess internal consistency of the scale, Cronbach's α was computed for the overall scale. To assess criteria-related validity, a series of independent sample t-test with family type (i.e., intact or non-intact family) as the independent variable and scores of each item of the scale as dependent variables were conducted.

RESULTS AND DISCUSSION

The data from this small convenience sample of adolescents showed that the scale had high internal consistency, with the overall Cronbach's α of .98. The mean inter-item

correlation was .51, which had moderate effect size. In addition, the mean corrected item-total correlation was .71. These indicators showed that the scale had excellent internal consistency.

For criteria-related validity, 43 out of 60 items as well as the total score across 60 items showed that adolescents in intact families were significantly different from adolescents in non-intact families. The effect size of the 43 items (i.e., Cohen's *d*) ranged .61 to 1.39, which was large. Table 1 lists the results of the independent sample *t*-test of each item.

Study 2

In this study, 253 participants were recruited from two local secondary schools. The participants were asked to fill in two sets of questionnaire within a two- week interval. While 53 participants failed to complete the first set of questionnaire, 63 participants failed to respond to the second set. The demographic information of the participants in both Time 1 and Time 2 are presented in Table 2. At Time 1, the average age of the participants was 14.70 (SD = 1.55; Min = 12; Max = 16), with 138 male participants and 66 female participants. At time 2, the average age of the participants were 14.58 (SD = 1.68; Min = 12; Max = 16), with 132 participants being male and 62 being female.

Invitation letters of Study 2 were sent to adolescents' parents through the secondary schools. The objective of the study was explained and confidentiality of the data was

emphasized in the letter. After obtaining written parental consent and adolescents’ own consent, participants were asked to fill in a short questionnaire.

Table 2. Demographic information of the participants in both Time 1 and Time 2

	Mean of Age	No. of Male	No. of Female	No. of Intact	No. of Non-Intact
Time 1	14.70 (SD = 1.55)	138	66	185	19
Time 2	14.58 (SD = 1.68)	132	62	176	18

The questionnaire at Time 1 contained the 8 items from a scale of adolescents’ perception of inter-parental non-conflict related attributes. The items were selected based on the criterion-related validity findings in Study 1. These items had the largest t-values in the study. The questionnaire also included other assessment tools listed below. All participants were also asked to report their demographic information, including age and gender.

Participants filled in the short questionnaire in a self-administered format. Adequate time was provided. Participants generally took around 20 minutes to complete the questionnaires. Internal consistency, test-retest reliability, construct validity and factorial validity of the scale were examined.

Instruments

Children’s Perceptions of Non-Conflict Related Attributes in Parental Relationship. Based on Study 1, 8 items with the largest differentiation power in terms adolescents perception of inter-were selected. The scale generally measures positive attributes of inter-parental relationship from adolescents’ perspective. Higher score represents higher level of perceived non-conflict related attributes.

Conflict intensity subscale of the Chinese version of Children’s Perceptions of Inter-parental Conflict Scale (C-CPIC-CI). Grych et al. [18] developed a 49-item child-completed questionnaire assessing 10 dimensions of inter-parental conflict, including frequency, intensity, content, resolution, threat, coping efficacy, content (child related vs. non-child related), triangulation, stability and self-blame. Research findings showed that CPIC possessed good psychometric properties. Besides, compared with other commonly employed indicators of marital conflict and satisfaction, Conflict intensity subscale scores were more predictive of child adjustment [18]. Higher score represents a higher level of perceived conflict intensity. The Chinese version of the scale was translated by Zhao and Mo [19] who found that Conflict intensity subscale is reliable and valid in Chinese samples across developmental ages.

Chinese version of Life Satisfaction Scale (C-LIFE). Diener et al. [20] developed the Satisfaction with Life Scale to assess global evaluation of quality of life. There are 5 items in the scale with a six-point scale. The scale was found to be internally consistent and valid in Chinese [21]. A higher LIFE scale score indicates a higher level of life satisfaction.

Chinese version of Hopelessness Scale (C-HOPEL). Beck, Weissman, Lester, and Trexler [22] developed the Hopelessness Scale (HOPEL) to measure the sense of hope in a person. The Chinese HOPEL scale was developed and proved to be reliable and valid by Shek [23]. A

higher HOPEL scale score indicates a lower sense of hope. Yip and Cheung [24] suggested a four-item Chinese version of the scale. They found that the four-item Chinese version predicted depression and suicide in Hong Kong Chinese sample.

Chinese version of short form of the Marlowe–Crowne Social Desirability Scale (CMCDS). The scale has 14 items which assess whether a person responds in a socially desirable manner [25]. The Chinese version of the Marlowe–Crowne Social Desirability Scale (Short Form) was reliable and valid in Chinese people [25].

Except CMCDS which was used at Time 2 only, all other instruments were used at both Time 1 and Time 2. To establish the convergent validity of the scale, it was expected that the mean scores of the scale assessing adolescent perceptions of inter-parental non-conflict related attributes would have negative relationships with mean scores of C-CPIC-CI and C-HOPEL but a positive relationship with C-LIFE at Time 1 and Time 2.

Results and Discussion

Results showed that scores of adolescents' perception of inter-parental non-conflict related attributes were not significantly related to the participants' gender, age, parental educational level, and family income.

Results showed that the scale had high internal consistency, with the overall Cronbach's α of .95 for both Time 1 and Time 2 data. The mean inter-item correlations were .70 for Time 1 and .69 for Time 2 data, which had strong effect size. In addition, the mean corrected item-total correlation coefficients were .81 for Time 1 and .82 for Time 2 data. These indicators showed that the scale had excellent internal consistency. To assess the temporal stability of the measure, test-retest reliability was performed. The correlation coefficient, the Pearson's r , between two equivalent tests was taken as an estimate of the reliability of the test. Test-retest reliability coefficient, in terms of Pearson's r was .81 ($p < .001$). Analyses using paired t-test showed that the Time 1 ($M = 3.92$) and Time 2 ($M = 3.88$) mean scale scores were not significantly different, $t(132) = .14$, ns . These findings suggested that the scale showed good test-retest reliability.

For the convergent validity of the proposed scale, correlation coefficients between C-CPIC-CI and C-LIFE, C-HOPEL and CMCDS were computed. For the Time 1 data, it was found that the total scores of adolescents' perception of inter-parental non-conflict related attributes showed a significantly negative relationship with the score of CPIC-CI and C-HOPEL but positive with the score of C-LIFE. The Pearson r were $-.41$ ($p < .01$), $-.40$ ($p < .01$), and $.60$ ($p < .01$) respectively, which were considered as a moderate effect size according to Cohen's [26] suggestion.

For Time 2 data, mean scores of adolescents' perception of inter-parental non-conflict related attributes showed a significantly negative relationship with CPIC-CI ($r = -.47$, $p < .01$) and HOPEL ($r = -.35$, $p < .01$) but positive with LIFE ($r = .58$, $p < .01$). These correlations were considered barely moderate to moderate in term of effect size (Cohen, 1988). The scores of adolescents' perception of inter-parental non-conflict related attributes was positively correlated with that of CMCDS. The Pearson r was $.32$ ($p < .01$). The correlation was considered to be weak [26].

To examine the underlying dimensionality of the scale, we used principal component analysis followed by varimax rotation. For Time 1 data, initial factor extraction, change of eigenvalue and the scree plot suggested a one-factor solution. The eigenvalue was greater than unity, and the solution explained 74.16% of the total variance. The loadings of all items exceeded .70. The factor had all 8 items. This factor corresponded to the domain of communication, appreciation, satisfaction and helping in content validation in Study 2.

For Time 2 data, initial factors extraction, change of eigenvalue and the scree plot also suggested a one-factor solution. The factor had eigenvalue greater than unity, and the solution explained 73.00% of the total variance. The loadings of all items exceeded .70. The factor had all 8 items. This factor corresponded to the domain of communication, appreciation, satisfaction and helping in content validation. Table 3 illustrates the rotated component matrix of the items at Time 1 and Time 2.

Table 3. Component matrix of revised adolescents' perception of inter-parental non-conflict related attributes for time 1 data

Items	Factor at Time 1	Factor at Time 2
1. My parents talk to each other and have fun together.	.803	.830
2. My parents talk to each other when having dinner.	.831	.819
3. My parents get along well.	.896	.857
4. My parents have good communication.	.844	.855
9. My parents express that the other party is a good partner.	.865	.849
10. My parents express their appreciation of each other.	.872	.881
16. My parents actively help when the other party faces difficulties.	.888	.869
20. My parents feel that the other is the ideal companion.	.885	.874

OVERALL DISCUSSION

In view of the non-existence of validated assessment tools for adolescents' perception on inter-parental non-conflict related attributes, the present paper describes two studies examining the psychometric properties of the scale. There are two unique characteristics of the studies. First, an indigenous measure of adolescents' perception of inter-parental non-conflict related attributes was employed. Second, reliability (internal consistency and test-retest reliability) and validity (convergent validity and factorial validity) were investigated.

The studies generated empirical evidence on the psychometric properties of adolescents' perception of inter-parental non-conflict related attributes, which is considered as pioneering in this field. The scale showed good results in internal consistency, test-retest reliability, convergent validity and factorial validity, suggesting that the scale possesses good psychometric properties. As related research in this area is almost non-existent, this study is an important addition to the literature.

Results of Study 1 indicated that items with highest ability to differentiate adolescents from intact and non-intact families mainly come from the domains of communication and satisfaction. This is highly consistent with the literature on marital quality, relationship and

interactions [15-17] as well as on positive relationship features of marriage [27-29], suggesting that communication and satisfaction are sensitive indices differentiating distressed from non-distressed couples from both couples' and adolescents' perspectives.

However, inconsistent with previous literature on the positive relationship features of marriage [27-29], results of Study 1 showed that appreciation and concern were also important elements of differentiating distressed from non-distressed couples because items from these two domains demonstrated high differentiation power. This supplements theorization and conceptualisation of positive relationship features of a marriage [27-29]. There are two possible explanations for this observation. First, the difference may be attributed to different perspectives between couples and adolescents. Previous studies on the positive relationship features of marriage mainly used couple samples whereas the present studies used data from adolescents. Empirically, Joshi [30] showed that children's perceptions of inter-parental relationships were different from those of parents.

Second, it may be due to cultural differences in perceptions of positive relationship features of marriage. Previous assessments of marital quality were developed in Western culture [31] whereas the scale of adolescents' perception of inter-parental non-conflict related attributes was developed and validated in a Chinese society. There are studies showing that conceptualisation of positive elements of romantic relationship and marriage varies across cultures [31-33]. Researchers are suggested to examine the role of appreciation and concern in differentiating distressed from non-distressed couples from both couples' and adolescents' perspective across cultures.

There are six implications of the present findings. First, the studies deepen our understanding of the dimensionality of the construct of adolescents' perception of inter-parental non-conflict related attributes. As there are only limited theoretical conceptualizations of the construct, the present findings sharpen our ideas on the underlying facets of inter-parental non-conflict related attributes. Second, the present findings provide evidence for an indigenous measurement tool that may be useful for further exploration of indigenous Chinese concepts as well as construction of Chinese family models. Third, a reliable and valid measurement tool may bring special value for further research on the association between inter-parental relationship and adolescents' development. Previous studies on the association between inter-parental relationship and adolescents' development focused on parental conflict [1, 2], with little attention paid to positive aspects of inter-parental relationship, including non-conflict-related attributes. The proposed measure developed in this study makes it possible to examine the unique contribution of different aspects of inter-parental relationship to adolescent development.

Fourth, practically speaking, the scale helps social workers enhance adolescents' mental health by teaching parents the skills that foster inter-parental non-conflict related attributes such as active response to partners' need and appreciation. Fifth, as a measure of positive feature of marriage from adolescents' perspective, the scale enables clinicians to assess how adolescents perceive non-conflict related family processes and design the intervention plan. The use of this measure in the context of an emotionally close relationship with the counselor may help more defensive adolescents deal with the resistance in talking about and facing poor inter-parental interaction [34]. This may be particularly important for Chinese people because inter-parental conflict behavior might not be a sensitive indicator of inter-parental relationship quality [12]. Absence of non-conflict related attributes may indicate poor inter-parental

interaction as perceived by children. Sixth, this measure could also be used as a means for children and adolescents to express their feelings about the marital quality of the parents [34].

There are several limitations of the present findings. First, as two adolescent samples were not randomly sampled, generalizability of the findings may be limited. Second, the small sample size in parent's study may restrict stability in factor analysis. Thus, there is a need to conduct factor analysis using larger samples. Third, research findings showed that adolescents' perception of inter-parental relationship and interaction was influenced by their developmental progress and cognitive maturity [35, 36] as well as the indicators under focus [37]. Therefore, the factor structures of the scale of adolescent perception of inter-parental non-conflict related attributes may vary across age and gender of adolescents [34]. It is essential to conduct further studies using multi-group confirmatory factor analysis to investigate the dimensionality of the scales with different samples of adolescents. Fourth, as only Chinese adolescents and parents in Hong Kong, we have to examine the generalizability of the findings in other contexts.

Despite the above limitations, the studies are pioneer in assessing the reliability, validity and dimensionality of the measure. It clearly demonstrates that the scale of adolescents' perception of inter-parental non-conflict related attributes possesses good psychometric properties that can be used objectively in Chinese parents and adolescent samples. As commented by Shek [14] that "there were few validated Chinese assessment measures and the effort to validate the developed measures was inadequate" (p. 282), the studies are regarded as positive response to Shek's suggestion.

ABSTRACT

The first training workshop for the Tin Ka Ping P.A.T.H.S. Project for 2015-2016 school year was held in December 2015 in Zhaoqing, mainland China. To gauge the impact of the training program, 134 participants completed a subjective outcome evaluation survey during the last training session. Results showed that the vast majority of trainees were highly satisfied with the training program regarding perceived program benefit, program quality, administrative arrangements, instructor performance, and their own performance. Consistent with the previous findings, overall satisfaction and the perceived benefits were positively predicted by the perceived program quality. Besides,

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

instructor quality, administrative arrangements, and participants' own performance also predicted perceived program benefits. The favorable evaluation findings suggested that the training program for Tin Ka Ping P.A.T.H.S. Project training program was well-designed and well received by the program participants in mainland China.

Keywords: professional training, subjective outcome evaluation, Tin Ka Ping P.A.T.H.S. Project, positive youth development

INTRODUCTION

The transition from childhood to adulthood is not an easy task for adolescents. During this transitional phase, adolescents face dramatic changes in every aspect of their life, including physical growth, sexual maturation, cognitive development, social development and emotional changes [1]. ADOLESCENTS going through such a turbulent transition period often engage in different risk behaviors and are vulnerable to developmental problems, such as mental health problems, addictive behaviors, self-harm behaviors, bullying behaviors and delinquent behaviors [2-5]. In view of these rising concerns, efforts to promote healthy adolescent development such as the development of positive youth development (PYD) programs have emerged. Unfortunately, programs devoted to reducing adolescent developmental problems and promoting positive adolescent development are grossly inadequate in different Chinese societies [6].

To promote positive youth development amongst Chinese adolescents in Mainland China, a PYD program entitled "Tin Ka Ping P.A.T.H.S. (Positive Adolescent Training through Holistic Social Programs) Project" was introduced in Mainland China with the financial support from the Tin Ka Ping Foundation. This Project was transplanted from the Project P.A.T.H.S., which is a systematic and holistic PYD program that has been implemented for Hong Kong junior secondary school students for many years. Studies utilizing a broad range of systematic evaluation strategies, including both quantitative and qualitative evaluation methods, have shown that the Project P.A.T.H.S. is effective in promoting the PYD and in slowing down the development of risk behavior among Hong Kong adolescents [7-10].

Tin Ka Ping P.A.T.H.S. Project is a curriculum-based universal program targeting all students studying in secondary schools. The curriculum is based on the 15 positive youth development constructs identified in the existing successful programs [11]. As a transplant of the Project P.A.T.H.S. in Hong Kong, the Tin Ka Ping P.A.T.H.S. Project has the benefit of learning from the experience in Hong Kong. With reference to the socio-cultural contexts in mainland China, the curriculum of junior secondary school program was adapted and modified. For example, the modified program incorporated traditional Chinese virtues and moral values, as well as topics relevant to the development of young people in mainland China. Besides the junior secondary school curriculum, the Research Team also developed curriculum materials for the senior secondary school program which are applicable to Secondary 4 to Secondary 6 students.

Table 1. The first training program of the Tin Ka Ping P.A.T.H.S. Project in Zhaoqing, mainland China

Junior Group

Day 1 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) Introduce the implementation progress of the Tin Ka Ping P.A.T.H.S. Project; and	1. Introduce the Tin Ka Ping P.A.T.H.S. Project and the professional team, ice-breaking exercise;
b) Offer opportunities for participants to share their experiences;	2. Explain how to use teaching materials and other resources of Tin Ka Ping P.A.T.H.S. Project;
	3. Introduce the Co-Walker Scheme.
	4. Schools presentation on:
	a. Experience of pilot implementation (3 schools);
	b. Implementation progress and achievements (5 schools);
	c. School policy and administration (4 schools);
	d. Teaching and training experience (5 schools).
Day 2 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) Demonstrate teaching techniques;	1. "Collaborative teaching" technique demonstration by participating schools;
b) Familiarize the participants with teaching methodology of the Tin Ka Ping P.A.T.H.S. Project; and	2. Lesson demonstration by participating schools;
	3. Group discussion and Q&A session;
	4. Wrapping up and Self-reflection.
Day 3 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) Offer opportunities for participants to share their experiences;	1. Schools presentation on teachers' personal growth;
b) Clarify participants' questions on project implementation; and	2. Discussion and Q&A session on project implementation; and
c) Familiarize the participants with the evaluation methods of Tin Ka Ping P.A.T.H.S. Project.	3. Interactive lecture on the evaluation instruments of the program (form A, form B, and weekly report) and data analysis methods;
	4. Wrapping up and Self-reflection; and
	5. Conclusion.

Senior Group

Day 1 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) Introduce the implementation progress of the Tin Ka Ping P.A.T.H.S. Project; and	1. Introduce the Tin Ka Ping P.A.T.H.S. Project and the professional team, ice-breaking exercise;
b) Offer opportunities for participants to share their experiences;	2. Explain how to use teaching materials and other resources of Tin Ka Ping P.A.T.H.S. Project;
c) Familiarize the teachers with the constructs and teaching units.	3. Introduce the Co-Walker Scheme.
	4. Schools presentation on implementation progress and achievement.
	5. Lecture on the constructs and the contents of Units.

d) Familiarize the participants with the evaluation methods of Tin Ka	4. Wrapping up and Self-reflection; and
	5. Conclusion.

Researchers suggest that five factors contribute to the implementation quality of PYD programs, including program, people, process, policy, and place (5Ps) [12]. Among them, “people” is one of the most significant elements for successful program implementation [13]. Studies also consistently showed that program effectiveness could be explained by the perceived quality of program implementers [14, 15]. Thus, effective training for program implementers is extremely important because program implementers must understand the philosophy of the program, program content and related theories, teaching philosophy and techniques, and related success factors. As such, systematic training for the implementers is an indispensable prerequisite for effective program implementation in Mainland China. Besides, potential program implementers should be properly empowered and motivated to teach the program, which is always taxing and challenging for the program implementers.

As training is regarded as the cornerstone of successful PYD programs, the Tin Ka Ping P.A.T.H.S. Project places a great emphasis on training program implementers. Before the formal launching of the project, four training workshops were conducted in 2014-2015 school year. In 2015-2016 school year, three 3-day training workshops were conducted. All potential program implementers and school management, including teachers and principals from 30 participating schools all over Mainland China joined the training. The first 3-day training workshop took place in December 2015 at Zhaoqing, Guangdong province. This training workshop was intended to help trainees to (a) understand the concepts and rationale of positive youth development and relevant research and program; (b) understand the nature of youth development and to develop positive attitudes to adolescent development; (c) appreciate the rationales, design, implementation, and evaluation of the Tin Ka Ping P.A.T.H.S. Project; (d) understand the training contents and activities developed; (e) review and obtain attitude, knowledge, and teaching skills that are beneficial to the success of the program implementation; and (f) develop a self-help network among the training participants [16]. The details about the schedule, themes, and contents of this training workshop are shown in Table 1.

To understand the effectiveness of the training programs, post-training evaluation is indispensable. According to Salas and Cannon-Bowers [17], program evaluation enables the researchers to understand whether the program objectives have been achieved. In particular, evaluation can help researchers understand the acquisition of teaching skills and identification with the training philosophy.

More importantly, evaluation helps to answer theoretical and practical questions of what factors (such as program quality, implementer qualities, perceived benefits of the program) are related to training impact. Similarly, Robson, Sebba, Mittler and Davies [18] pointed out that training evaluation is essential because it helps identify what works and what does not work before program implementation.

To understand the effectiveness of training programs for the Tin Ka Ping P.A.T.H.S. Project, subjective outcome evaluation was conducted for all the training programs where participants' views toward the training (e.g., instructor quality and program quality), benefits of the training, satisfaction toward the program administrative arrangements and their own performance during training were the focuses in the evaluation study. There are several justifications for using subjective outcome evaluation [19]. First, it is not expensive to carry out. Second, it is an efficient way to understand the personal views of the trainees. Third, instead of relying on the evaluators' judgment, the voice of service recipients can be heard

[19]. Fourth, there is evidence suggesting that subjective outcome evaluation is closely associated with objective outcome evaluation findings [20, 21]. In this paper, evaluation findings from the first training workshop held in Zhaoqing in December 2015 are reported.

METHODS

In the school year of 2015-2016, three training workshops were held for implementers of the Tin Ka Ping P.A.T.H.S. Project in China in different cities, including Zhaoqing, Shaoguan, and Changchun. For the first workshop, a total of 166 teachers from 25 Junior Secondary schools and 19 Senior Secondary schools registered. The workshop lasted for 3 days in Zhaoqing, China. The participants were invited to fill in a subjective outcome evaluation questionnaire at the last session of the training workshop. One hundred and thirty-four questionnaires were collected finally. Not all participants responded because some of them left early due to transportation constraints. Among the respondents, 40 were males (29.9%) and 94 were females (70.1%). Almost all respondents were teachers ($n = 133$), apart from one school administrator. Forty-two of them were from senior secondary school and 92 were from junior secondary school. The average work experience for the teachers was 14.75 years ($SD = 8.37$).

Instruments

The subjective outcome evaluation questionnaire was utilized to assess participants' perceptions of the program content, instructor quality, administrative arrangement, and their own performance. A total of 31 items on a 5-point Likert-scale and two open-ended questions were included in the questionnaire. Regarding the two open-end questions, participants were asked about the things they most appreciated and the areas that they think need further improvement. In the present study, only the quantitative rating scales were analyzed.

There are four parts in the rating scales. The first part measures participants' perception of the training program content, including program benefits (9 items), program quality (5 items), and overall satisfaction (2 items). The second part measures participants' satisfaction with the program instructors (5 items). The third part assesses participants' satisfaction of program administrative arrangements (6 items). The last part measures participants' perceptions of their own performance in the workshop (4 items). Participants were asked to respond all items according to their own perceptions and feelings from "1 (strongly disagree/very dissatisfied)" to "5 (strongly agree/very satisfied)". The items can be seen in the tables. Previous training evaluation studies showed that the scale has achieved good psychometric properties [22-25].

RESULTS

All subscales and the overall scale were proven to be reliable, according to the results of reliability analyses. As shown in Table 2, the Cronbach's alpha ranged from .65 to .91 for all

the subscales. The overall rating scale also showed good internal consistency ($\alpha = .95$). The mean score for every subscale in both senior and junior secondary schools exceeded 4.0 with 5.0 as the maximum score, indicating that respondents generally had high satisfaction ratings on the program content, instructor quality, administrative arrangement, and their own performance. A one-way ANOVA was performed to compare the satisfaction ratings between senior and junior secondary school teachers. No significant differences were found which suggest that the satisfaction levels of the junior and senior year students over different domains were similar.

Table 2. Means, standard deviations, Cronbach's alphas, and mean of inter-item correlations and the comparison between Senior and Junior Secondary school participants

Subjective Outcome Evaluation Scales	Total (N = 134)		Senior (N = 42)		Junior (N = 92)		F
	M (SD)	α (Mean ^a)	M (SD)	α (Mean ^a)	M (SD)	α (Mean ^a)	
Program content (16 items)	4.33 (.37)	.91 (.38)	4.30 (.35)	.89 (.34)	4.34 (.38)	.92 (.41)	.29
Perceived benefits (9 items)	4.40 (.40)	.86 (.41)	4.40 (.38)	.86 (.42)	4.40 (.40)	.87 (.42)	.00
Program quality (5 items)	4.27 (.41)	.74 (.37)	4.20 (.40)	.72 (.34)	4.30 (.41)	.75 (.38)	1.51
Overall satisfaction (2 items)	4.16 (.49)	.65 (.49)	4.13 (.46)	.47 (.31)	4.18 (.51)	.72 (.56)	.35
Program instructor (5 items)	4.35 (.44)	.83 (.51)	4.31 (.41)	.78 (.43)	4.37 (.45)	.86 (.56)	.49
Administrative arrangements (6 items)	4.15 (.60)	.91 (.63)	4.09 (.60)	.91 (.65)	4.19 (.60)	.91 (.62)	.82
Self-performance (4 items)	4.15 (.47)	.83 (.55)	4.14 (.44)	.78 (.47)	4.16 (.49)	.85 (.59)	.03
Total scale (31 items)	4.28 (.38)	.95 (.37)	4.24 (.36)	.94 (.34)	4.29 (.38)	.95 (.38)	.52

In Table 3-6, the participants' positive perceptions (i.e., ratings of 4.0 and 5.0 scores) of the training program in different aspects are presented. Table 2 shows that almost all participants agreed that the training program had strengthened their understanding of the nature of adolescent development (97.76%) and positive youth development (96.27%), and helped them cultivate a positive attitude to adolescent development (97.01%). Generally speaking, most of the respondents agreed that the training program benefited them in several domains (95.35%). Participants also had a quite positive evaluation of program quality (82.58%) and they agreed that the training methods and activities were appropriate (96.27%).

Overall speaking, the participated teachers had a very positive perception of the instructor(s)' teaching performance (99.25%). They perceived that the instructor(s) showed good professional attitude (99.25%) and had a good mastery of the curriculum (96.27%). As for the satisfaction ratings on administrative arrangements, 82.84% of the participants were satisfied with the information obtained before attending the workshop (82.84%) and the reception provided by training team (84.33%). Besides, the participants were also satisfied with their own performance (82.84%). After attending the training program, 91.79% of the participants had confidence in program implementation.

As demonstrated in Table 7, significant positive correlation coefficients (r s ranged from .46 to .78, p s < .001) were found among the key evaluation components, including program quality, instructor quality, perceived benefits, overall satisfaction, self-performance, and administrative arrangement. Two multiple regression analyses were further conducted to test

the relationships among the ratings of participants' satisfaction towards different domains of the training program (see Table 8). Results showed that perceived benefits were significantly predicted by perceived program quality ($\beta = .30, p < .001$), perceived administrative arrangements ($\beta = .24, p = .001$), and perceived self-performance ($\beta = .27, p < .001$), and marginally significantly predicted by perceived instructor quality ($\beta = .15, p = .051$). The whole model explained 61% of the variance of the perceived benefits of the workshop. Besides, overall satisfaction was significantly predicted by the perceived program quality ($\beta = .61, p < .001$). The whole model explained 64% of the variance of overall satisfaction.

Table 3. Summary of the positive views (options 4-5) of the participants towards the training program content

Perceptions of the Program Content			N	Agree (4)		Strongly Agree (5)		Positive Response (Options 4-5)		M	SD
				n	%	n	%	n	%		
Perceived Benefits ^a			129					123	95.35	4.40	.40
1.	It has strengthened my understanding of the nature of adolescent development.		134	60	44.78	71	52.99	131	97.76	4.51	.55
2.	It has helped me to cultivate positive attitude to adolescent development.		132	59	44.03	71	52.99	130	97.01	4.52	.53
3.	It has strengthened my understanding of positive youth development, including its concept, design, and research.		133	65	48.51	64	47.76	129	96.27	4.45	.56
4.	It has helped me to understand the Project P.A.T.H.S., including its basic philosophy, design, implementation, and evaluation.		134	66	49.25	63	47.01	129	96.27	4.43	.57
5.	It has strengthened me to understand the content of the Tier 1 Program.		134	77	57.46	54	40.30	131	97.76	4.37	.56
6.	It has helped me to acquire the attitude, knowledge, and skills that are conducive to the successful implementation of the Tier 1 Program.		134	74	55.22	46	34.33	120	89.55	4.24	.63
7.	It has helped me to establish self-help support network and share teaching experiences among the program participants.		134	75	55.97	49	36.57	124	92.54	4.29	.60
8.	It has promoted self-reflection.		133	61	45.52	67	50.00	128	95.52	4.47	.57
9.	It has helped me to recognize factors affecting teaching.		133	76	56.72	49	36.57	125	93.28	4.31	.58
Program Quality ^a			132					109	82.58	4.27	.41
1.	The training methods and activities are appropriate (e.g. lecture, games, group discussion).		134	71	52.99	58	43.28	129	96.27	4.40	.56
2.	Training time is appropriate.		134	84	62.69	24	17.91	108	80.60	3.98	.63
3.	It has met my expectation.		132	83	61.94	31	23.13	114	85.07	4.10	.60
4.	There was much peer interaction amongst participants.		133	68	50.75	59	44.03	127	94.78	4.40	.58
5.	Instructor(s) encouraged participants to do the best.		134	63	47.01	67	50.00	130	97.01	4.47	.56
Overall Satisfaction ^a			133					111	83.46	4.16	.49
1.	Overall speaking, I am satisfied with the training program.		134	87	64.93	42	31.34	129	96.27	4.28	.53
2.	I think participants are satisfied with the training program.		133	83	61.94	29	21.64	112	83.58	4.06	.61
Perceptions of the Program (Whole Scale) ^a			129					115	89.15	4.33	.37

Note: ^a: Scores on the scale/subscale higher than or equal to 4 were treated as positive views.

Table 4. Summary of the positive views (options 4-5) of the participants towards the program instructor(s)

Perceptions of the Program Instructor(s)	N	Agree (4)		Strongly Agree (5)		Positive Response (Options 4-5)		M	SD
		n	%	n	%	n	%		
1. The instructor(s) had good mastery of the curriculum.	134	86	64.18	43	32.09	129	96.27	4.28	.53
2. The instructor(s) understood the needs of participants.	134	74	55.22	39	29.10	113	84.33	4.13	.66
3. The instructor(s) showed good professional attitude.	134	43	32.09	90	67.16	133	99.25	4.66	.49
4. The instructor(s)' teaching was clear and easy to understand.	133	79	58.96	39	29.10	118	88.06	4.18	.61
5. Overall speaking, I have positive evaluation of the instructor(s)' teaching performance.	134	64	47.76	69	51.49	133	99.25	4.51	.52

DISCUSSION

The Tin Ka Ping P.A.T.H.S. Project aims to promote holistic development of Chinese adolescents. As a pioneering PYD program in mainland China, systematic training for the potential implementers is a must [26]. As reviewed by Lauer et al. [27], short-term face-to-face professional development training programs with effective design features have steady positive impacts on education workers. A well-designed pre-service training could serve to enhance participants' knowledge and beliefs, cultivate their professional competency and skills, and further to improve their teaching practices [28]. In the present study, the effectiveness of a training program for Tin Ka Ping P.A.T.H.S. Project was evaluated. Responses to a subjective outcome evaluation from 134 participants revealed that the training program in Zhaoqing city in the year 2015 was successfully and smoothly implemented. In agreement with the evaluation studies [22-25] for the training programs in the preparatory year (i.e., 2014-2015 school year), participants expressed overwhelmingly positive perceptions towards the first training program in the full implementation year.

Several observations can be highlighted from the findings. First, favorable reactions towards the program benefits were found. Participants agreed that the training program had strengthened their professional attitude, knowledge, and skills in positive adolescent development. Second, many participants agreed that the training program promoted their self-reflection. As the Tin Ka Ping P.A.T.H.S. Project emphasizes much on the importance of reflection in students, the potential program implementers must be able to appreciate the value of reflection. Third, the respondents opined that program quality, instructor quality, and administrative arrangements had successfully met participants' expectations. These observations echo the model proposed by Shek and Sun [12, 13] that "program," "process,"

and “people” are important determinants of success of PYD programs. Theoretically, it can be argued that program instructors and the program itself serve as a bridge to motivate and encourage participants to have self-reflection and to establish their own peer networks. Finally, most of the participants were satisfied with their own performance in the training program. Such experience would obviously promote the self-efficacy of the potential program implementers to facilitate them to apply the knowledge and skills acquired from training to teach and help the youths.

Besides the above observations, several findings of the study deserve further attention. First, comparison of the perceptions between participants in senior and junior sections showed no significant differences. The findings suggested that junior and senior high school teachers perceived the training programs positively and the findings were consistent with findings in previous studies [22-25]. Second, regarding predictors for perceived benefits, besides program quality, the other three components (including instructor quality, administrative arrangements, and participants’ own performance) also played a positive role. These findings suggested that multiple factors should be taken into account when examining the impact of training programs.

It is noteworthy that there are several limitations of the present study. First, a general criticism on subjective outcome evaluation is its deficiency in predicting future behavior or performance [29]. Obviously, it would be helpful to look at the change of the trainees in the real world using objective outcome evaluation such as follow-up observations of trainees. The association between subjective and objective outcome evaluation findings could help verify the favorable conclusions in the present study. Second, the quantitative evaluation could hardly explain the complexity and details of participants’ feelings and reactions. Hence, qualitative data collected through structured interviews and focus groups could be constructive and helpful. Third, increasing sample size could better generalize the findings. Despite these limitations, the present positive findings showed that the training program for the Tin Ka Ping P.A.T.H.S. Project training program in Zhaoqing was well received and welcomed by the potential implementers in mainland China.

ACKNOWLEDGMENT

The preparation for this paper and the Tin Ka Ping P.A.T.H.S. Project are financially supported by the Tin Ka Ping Foundation.

ABSTRACT

Subjective outcome evaluation approach was used to investigate the participants' views of Tin Ka Ping P.A.T.H.S. Project training program held in Shaoguan, China. A total of 63 junior teachers and 63 senior teachers responded to the satisfaction questionnaires. Results revealed that almost all participants highly appreciated all components of the program. Compared to participants in the senior high school training program, participants in the junior high school training program rated the program in a more favorable manner. Consistent with previous studies, perceived program quality positively predicted both perceived benefits and overall satisfaction. Perceived instructor quality and perceived self-performance were also significant predictors of perceived

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

benefits of the program. The present study suggests that the training program of Tin Ka Ping P.A.T.H.S. Project in Shaoguan was effective in promoting the knowledge, attitudes, and skills of the participants in the training program.

Keywords: Tin Ka Ping P.A.T.H.S. Project, training evaluation, adolescent, positive youth development

INTRODUCTION

Adolescents are important assets for a society if they can develop their potential to the fullest extent. However, they can also be burdens for the society if they fail to develop in a healthy way [1]. During their transition to adulthood, contemporary adolescents face many challenges, such as high expectations from parents, stressful school life, temptations such as Internet addiction and moral confusion, and highly competitive job market [2]. Under such pressure, adolescents are vulnerable to a plethora of developmental issues, such as substance abuse, early sexual involvement, addictive behaviors, self-harm/suicide intentions or behaviors, and juvenile crimes [3, 4]. Based on a systematic review conducted by Muehlenkamp and her colleagues [3], non-suicidal self-injury and deliberate self-harm behaviors were prevalent among adolescents across nations, with an average rate of 18.0% and 16.1%, respectively. In China, Shek and Yu [5] did a survey among over 3,000 secondary school students in Hong Kong. They found that during the year of 2011, 32.7% of the participants reported at least one form of deliberate self-harm behaviors. Furthermore, they found that self-harm and suicidal signals were more likely to be present among students with lower cognitive, behavioral, and emotional competencies. Besides self-harm behaviors, Internet addiction has also become a common health problem for adolescents [4]. Research findings showed that the prevalence of addictive Internet use was high in both mainland China (10%) and Hong Kong region (16%).

Two main approaches have been adopted to “solve” adolescent developmental issues [6]. Initially, the prevention science approach was proposed for reducing problematic behaviors of troubled adolescents. Single-problem-focused prevention programs emerged since the 1980s in response to the existing crises, such as substance abuse [7], teenage pregnancy [8], academic failure [9], dysfunctional family [10], and mental health problems [11]. However, evaluation studies showed that the positive effects of “problem-based” prevention programs were not ideal [e.g., 12]. Though longitudinal studies and evaluation findings were later incorporated to help service providers and researchers diagnose the predictors of specific problem behaviors [13], it is still uneconomical and impractical to develop prevention programs for each specific adolescent problem behavior. Therefore, the positive youth development (PYD) approach emerged as an alternative approach to promote and enhance adolescents’ psychosocial competencies from an ecological perspective [14]. As stated by Larson [14], “development, after all, is a process of growth and increasing competence. In the important subdomain of social and emotional development, however, we are often more articulate about how things go wrong than how they go right” (p. 170). Therefore, instead of viewing young people as troublesome, PYD approach emphasizes the intrinsic strengths and values of youths [9, 15]. Many PYD programs aim to reduce youth problems by promoting their strengths and competencies. For example, a PYD program enhancing effective decision-

making skills successfully reduced adolescents' use of drugs, alcohol, and marijuana one year after commencement of the program [15].

Although the notion of PYD has been widely accepted [16], insufficient work has been done in developing and implementing PYD programs in different Chinese contexts [17]. Shek and his colleagues have led a Project entitled "P.A.T.H.S. (Positive Adolescent Training through Holistic Social Programmes)" in Hong Kong. The P.A.T.H.S. Project aims to promote the holistic development of adolescents in Hong Kong by providing both school-based and community-based programs [17-19]. Evaluation studies have shown that the P.A.T.H.S. Project received high satisfaction ratings from various stakeholders, and consistently demonstrated the success of the project in reducing the growth of adolescent risk-taking behaviors such as drug use and Internet addiction, and promoting the positive psychosocial constructs including cognitive competence, social and emotional competence, and moral competence [20-23].

Obviously, it is important to ask how we can disseminate the successful experience of the Project P.A.T.H.S. to other Chinese communities. Upon the invitation of Tin Ka Ping Foundation, the Research Team adapted and implemented the Project P.A.T.H.S. in mainland China since 2011. After the initial trial from 2011 to 2014 and the training provided to the potential schools in the 2014-15 school year, the project was in a full implementation mode that engaged around 30 schools in China participating in the project. As pointed out by Shek and Sun [24], "people" is the most important factor that influences program quality. Besides, previous studies have found that implementer performance could explain the effectiveness of a program to a great extent [23, 25]. Obviously, implementers act as gatekeepers to transmit the program content from the program developers to the program receivers. Hence, implementers' mastery of the knowledge and their understanding of the program rationales are the prerequisites of effective program implementation [26].

Given the above considerations, starting from the preparatory year (i.e., 2014-2015 academic year) of the full implementation of the project, the Research Team began to offer training programs for implementers, including teachers, social workers, and school principals. During 2014-2015 academic year, four training workshops were held in different cities in mainland China, including Shanghai, Suzhou, and Chongqing. These training programs attempted to fulfill the following objectives: 1) strengthening implementers' understanding of the nature of positive youth development; 2) cultivating and summarizing the rationales, concepts, and latest development of the Tin Ka Ping P.A.T.H.S. Project; 3) offering opportunities for implementers to share successful experiences during the implementation; 4) reviewing the obstacles and obtain feedbacks from frontline implementers; 5) motivating implementers to have self-reflections; and 6) facilitating implementers to develop peer networks among the training participants and learn collaborative teaching strategies [27].

Shek and Wai [28] did a systematic review of training programs in positive youth development programs. They found that although there was a proliferation of PYD programs in the recent two decades, few offered systematic training programs for the potential program implementers, and even fewer evaluated the effectiveness of the training programs [29, 30]. However, training program evaluation deserves much more attention than it actually receives because once the PYD program is off-course, the intended learning effects may disappear [28]. Therefore, evaluating the effectiveness of the training program can give the program developers some ideas whether the potential program implementers indeed understand the program and implement it according to the philosophy of the program. Besides, feedbacks

from the trainees also shed light on future improvement of the training content, training method, and trainers' performance [27].

Different aspects have been assessed in the existing training evaluation studies. For example, Kealey et al. [31] evaluated the in-service training program for a school-based smoking prevention by assessing teachers' perception of the content of the program, perceived usefulness of the training, and quality of the facilities and arrangements. Nunnery et al. [32] evaluated teachers' perceptions and feelings of a pre-implementation training in the domains of quality of training (organization, trainers' performance, and perceived effectiveness), participants' self-perception, and the enthusiasm and confidence towards implementing. However, very few evaluation studies on PYD training program have been published. To fill in this research gap, Shek [33] developed an evaluation questionnaire to test the participants' perceptions of the training program for Project P.A.T.H.S. in Hong Kong. There are four main domains in the questionnaire, including perceptions of the training program (e.g., objectives, activity formats, and designs), instructor quality, own performance, and administrative arrangements. Evaluation findings supported that the training programs for Project P.A.T.H.S. were effective and satisfactory [26, 33]. The questionnaire has also shown good reliability and validity based on the data collected in mainland China. The subjective outcome evaluation findings collected in the academic year of 2014-2015 showed that the related training programs were successful [34-37].

It is noteworthy that some improvements were made for the training program content in the year 2015-2016, such as acquainting new-added teaching materials, sharing successful implementing experiences in mainland China, and separating training workshops for senior and junior secondary teachers. Therefore, to replicate the positive findings in previous years and to examine whether the implementation of the training program in the full implementation year (i.e., the academic year 2015-2016) was equally effective and smooth, the present study attempted to evaluate the second training program in 2015-2016 academic year held in Shaoguan of mainland China. The details of the training program can be seen in the appendix.

METHODS

The second training workshop for the Tin Ka Ping P.A.T.H.S. Project in China in 2015-16 school year was held in Shaoguan. The workshop lasted three days. Two separate training sessions were held in parallel for junior secondary school teachers and senior secondary school teachers, respectively. A total of 108 teachers from 24 junior secondary and 81 teachers from 23 senior secondary schools participated in the training program. At the last session of the workshop, the participants were invited to fill in a structured subjective outcome evaluation questionnaire. Some teachers were not able to complete the questionnaire since they left earlier because of transportation reasons. Finally, a total of 126 questionnaires were collected from 63 junior teachers and 63 senior teachers. Among all the respondents, 38 (30.2%) were males and 88 (69.8%) were females. A large proportion (59.5%) of the teachers had more than 10 years of extensive teaching experience. The average teaching experience of the participants was 13.35 years ($SD = 9.48$).

Instruments

To assess participants' perceptions of the training program in the present study, five parts were included in the questionnaire:

1. Perception of the training program content (16 items), including the perceived program quality (5 items), perceived program benefits (9 items), and overall satisfaction (2 items).
2. Perception of the program instructor (5 items).
3. Perception of the administrative arrangements (6 items).
4. Perception of own performance (4 items).
5. Two open-ended questions, including the things that they most appreciated and the areas that they think need further improvement during the workshop.

For the first four parts, participants were asked to rate their agreement/satisfaction on a 5-point Likert scale (from 1 = strongly disagree/very dissatisfied to 5 = strongly agree/very satisfied), with a higher score indicating a more positive perception. The rating for each scale/subscale was indicated by the average score of corresponding items. The present study attempted to investigate participants' perceptions of the program in terms of content, instructor, administrative arrangements, and self-performance. Hence, only data based on the rating scales were analyzed.

RESULTS

The overall scale and all subscales were reliable according to the results of reliability analyses as shown in Table 1. Except the overall satisfaction subscale, the overall rating scale and all subscales showed medium to high internal consistency with Cronbach's alpha ranging from .75 to .93. For the overall satisfaction subscale, insufficient number of items (only two items) could possibly account for the relatively low reliability (α ranged from .47 to .63) [38].

Table 1. Cronbach's alphas and mean of inter-item correlations of the scales/subscales

Subjective Outcome Evaluation Scales	Total (n= 126)		Senior (n= 63)		Junior (n= 63)	
	α	Mean [#]	α	Mean [#]	α	Mean [#]
Program content (16 items)	.91	.39	.90	.37	.91	.40
Program quality (5 items)	.76	.41	.75	.39	.76	.40
Perceived benefits (9 items)	.86	.40	.86	.41	.86	.40

Total Scale ^a															

Note: ^a: Scores on the scale higher than or equal to 4 were treated as positive views.

To have a comprehensive understanding of the participants' satisfaction with the training program, the numbers and percentages of positive ratings (i.e., options 4 and 5 on the 5-point Likert scale) on each scale/subscale were aggregated as shown in Table 2-5. In general, both junior and senior teachers rated over 4.0 on every subscale with 5.0 as the maximum score, indicating their high satisfaction with the program content, instructor quality, administrative arrangement, as well as their own performance.

Specifically, Table 2 illustrates that over 80% of the participants expressed positive views towards almost every aspect of the program quality, except for the training time (71.77%). Regarding perceived benefits of the program, almost all participants (99.19%), especially participants in junior session (100.0%), agreed that the training workshop had strengthened their understanding of the nature of adolescent development and it had helped them cultivate positive attitudes to adolescent development. In addition, over 80% of the participants had overall satisfaction with the training program.

Participating teachers (83.87%), especially junior school teachers (92.06%), expressed highly positive ratings towards the program instructors. Almost all participants agreed that the instructors had a good mastery of the curriculum (97.58%) and they had shown good professional attitude (98.39%). With respect to the administrative arrangements, approximately 90% of the participants had overall satisfaction. Besides, over 90% of the participants held positive views towards the workshop assigned. Results in Table 5 indicate that 96.83% of the participants were willing to apply the specific skills and theories learned from this training program, and 89.68% of the participants participated actively during the discussion.

To compare the perceptions between senior and junior school teachers, a MANOVA analysis was performed. As demonstrated in Table 6, significant differences were found in the perception of program quality ($F(1,122) = 4.86, p = .029, \eta_p^2 = .038$), perceived administrative arrangements ($F(1,122) = 5.14, p = .025, \eta_p^2 = .040$), and the total score ($F(1,122) = 4.77, p = .031, \eta_p^2 = .038$). Marginally significant difference was found in perceived program instructor attributes ($F(1,122) = 3.82, p = .053, \eta_p^2 = .030$). In general, the training program for junior teachers received relatively higher satisfaction ratings than did the program for senior teachers, although the satisfaction ratings can be regarded as quite positive.

Table 6. The comparison between Senior and Junior Secondary school participants on the perceptions of the training program

Subjective Outcome Evaluation Scales	Senior (n = 63)		Junior (n = 63)		F	η_p^2
	M	SD	M	SD		
Program content (16 items)	4.25	.37	4.36	.40	2.24	.018
Program quality (5 items)	4.17	.45	4.35	.46	4.86*	.038
Perceived benefits (9 items)	4.34	.39	4.39	.41	.58	.005
Overall satisfaction (2 items)	4.07	.42	4.21	.54	2.35	.016
Program instructor (5 items)	4.30	.45	4.45	.44	3.82 [†]	.030
Administrative arrangements (6 items)	4.04	.56	4.26	.49	5.14*	.040
Self-performance (4 items)	4.12	.50	4.26	.49	2.22	.018
Total scale (31 items)	4.19	.36	4.34	.35	4.77*	.038

Note: * $p < .05$, [†] $p = .053$.

Table 7. Correlations among the key evaluation components

Variables	M	SD	1	2	3	4	5	6
Program quality (5 items)	4.26	.46	-					
Program benefits (9 items)	4.36	.40	.72***	-				
Program instructor(s) (5 items)	4.38	.45	.62***	.58***	-			
Administrative arrangement (6 items)	4.15	.53	.43***	.35***	.35***	-		
Self-performance (4 items)	4.19	.50	.61***	.64***	.37***	.37***	-	
Overall satisfaction (2 items)	4.14	.48	.71***	.65***	.50***	.40***	.50***	-

Note: *** $p < .001$.

Table 8. Multiple regression analyses predicting perceived benefits and overall satisfaction

Predictors	Perceived Benefits				Overall Satisfaction			
	<i>B</i>	<i>SE</i>	β	R^2	<i>B</i>	<i>SE</i>	β	R^2
Program quality	.34	.08	.39***	.613	.49	.11	.47***	.548
Instructor quality	.20	.07	.23**		.00	.09	.003	
Administrative arrangements	-.01	.05	-.02		.10	.06	.11	
Self-performance	.26	.06	.33***		.01	.08	.01	
Perceived benefits					.32	.12	.27**	

Note: * $p < .05$; ** $p < .01$; *** $p < .001$.

Pearson correlation analyses revealed that the key evaluation components, including perceived program quality, program benefits, program instructor, administrative arrangement, self-performance, and overall satisfaction, were significantly and positively correlated with each other (r s ranged from .35 to .72, p s $< .001$; see Table 7). Two multiple regression analyses were further performed to examine the predicting effects of the key evaluation components for perceived benefits and overall satisfaction (see Table 8). Results revealed that perceived benefits were significantly predicted by perceived program quality ($\beta = .39$, $p < .001$), instructor quality ($\beta = .23$, $p = .002$), and perceived self-performance ($\beta = .33$, $p < .001$), but not perceived administrative arrangements ($\beta = -.02$, $p = .772$). The whole model explained 61.3% of the variance of perceived benefits of the training program. Besides, overall satisfaction was significantly predicted by perceived program quality ($\beta = .47$, $p < .001$) and perceived program benefits ($\beta = .27$, $p = .008$). The whole model explained 54.8% of the variance of overall satisfaction.

DISCUSSION

There has been a shifting from problem-oriented to strength-oriented interventions for young people in Western societies in recent decades [39]. However, there is a lack of validated and effective positive youth development (PYD) programs in China [40]. The Tin Ka Ping P.A.T.H.S. Project was carried out to fill this gap which attempted to promote positive development in Chinese adolescents. Numerous researchers have reiterated the importance of professional training and development for youth workers [29, 31, 41]. For example, Bowie and Bronte-Tinkew [41] pointed out that effective pre-service and in-service training for youth workers not only benefit individual trainees but also improve program

quality. As training is important, the current study evaluated the effectiveness of the training program for potential program implementers in the “Tin Ka Ping P.A.T.H.S. Project” in China based on the responses of 126 participants.

The present findings suggest that the training program in Shaoguan in 2016 was an overall success. Generally speaking, feedbacks from the program participants were extremely positive. Consistent with the evaluation studies for the training programs in the previous year [34-37], participants highly appreciated every component of the program. Specifically, a considerable proportion of the participants acknowledged the benefits of the training program. They strongly agreed that the training workshop helped them strengthen professional skills and cultivate positive attitudes to adolescent development. Besides, participants had fairly positive perceptions towards program quality, instructor performance, and program administrative arrangements. The findings suggest that the training program for the Tin Ka Ping P.A.T.H.S. Project was well designed and implemented, and the instructors showed professional attitudes and good performance. Furthermore, most of the teachers expressed their satisfaction with their own performance during the training program. Almost all participants expressed their willingness to apply the learned skills and theories in providing service and help to adolescents.

Although the perceptions of the participants in the junior high school program and the senior high school program were fairly positive, participants in the junior high school program had more positive responses than did participants in the senior high school program. A possible explanation for this observation may be due to differences in teaching materials. The teaching materials for junior school students have been used and validated through over ten years’ implementation of the “P.A.T.H.S. Project” in Hong Kong. However, the teaching materials for the senior high school program are newly developed for mainland Chinese students, which are trial version only. Hence, potential implementers from senior school may still have concerns about the program content while junior teachers may not. Nevertheless, differences between senior and junior training sessions were not found in the first training program in the year 2015-2016 at Zhaoqing [42]. Therefore, the present finding should be treated as tentative which requires replication.

Consistent with previous studies [34-36], participants’ overall satisfaction was predicted by perceived program quality and perceived benefits of the program in the current study. It implies that participants’ endorsement of the program content and rationales is indispensable for a successful training program. Furthermore, participants’ perceived benefits of the program was positively predicted by perceived program quality, perceived instructor quality, and perceived self-performance. These findings have some implications for the design of training programs with benefits to trainees. First, the program itself should include rich and suitable materials. Second, the instructors should show professional attitudes and skills. Finally, the program should promote participants’ engagement in the training and their self-efficacy. As reflected in the 5 Ps theory proposed by Shek and Sun [24], the importance of “program,” “people,” and “process” elements are highlighted in the present study.

Three limitations of the present study should be addressed in future studies. First, the participants’ extremely positive responses may be due to demand characteristics. For example, the participants might rate positively on the survey because they wish to play the role of good program participants. Hence, measures assessing demand characteristics should be included in future studies. Second, as we could only access potential implementers’ perceptions in the present study, this would not be sufficient to enable the Research Team to

claim that the Tin Ka Ping P.A.T.H.S. Project is beneficial for the youths. As such, follow-up outcome evaluation studies should be conducted. Third, a larger sample size could give a clearer picture about the views of the trainees. Despite the above-mentioned limitations, the present study gives support to the effectiveness of the Tin Ka Ping P.A.T.H.S. Project training program in Shaoguan which paves the way for the successful implementation of the project in China.

APPENDIX

The second training program of the Tin Ka Ping P.A.T.H.S. Project in the 2015-2016 school year in Shaoguan, mainland China

Junior Group

Day 1 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) Introduce the latest advances of the Tin Ka Ping P.A.T.H.S. Project during the full implementation phase (2015-2016); b) Offer opportunities for school delegates, school principals, and experienced teachers to share their implementation experiences; and c) Familiarize the teachers with the constructs and teaching units.	1. Introduce the Tin Ka Ping P.A.T.H.S. Project and the professional team; 2. Warm-up activities; 3. Introduce the training schedules of the Project; 4. Guide the participants how to use the updated teaching materials and other resources of Tin Ka Ping P.A.T.H.S. Project; 5. Introduce the Co-Walker Scheme; 6. Introduce the results of first training program evaluation; and 7. Lecture on the rationales and the frameworks of units.
Day 2 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) School delegates share their teaching experiences and demonstrate teaching techniques; and b) Familiarize the participants with teaching methodology of the Tin Ka Ping P.A.T.H.S. Project;	1. Lesson demonstration by school delegated from participating schools; 2. Group discussion and Q&A session; and 3. Wrapping up and Self-reflection.
Day 3 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) Familiarize the teachers with the constructs and teaching units; b) Clarify participants' questions on project implementation; and c) Familiarize the participants with the evaluation methods of Tin Ka Ping P.A.T.H.S. Project.	1. Lecture on the constructs of "Resilience (RE)" and the contents of units; 2. Lecture on the constructs of "Emotional Competence (EC)" and the contents of units; 3. Lecture on the constructs of "Prosocial Involvement (PI)" and the contents of units; 4. Lecture on the constructs of "Behavioral Competence (BC)" and the contents of units; 5. Interactive lecture on the evaluation instruments of the program (form A, form B, and weekly report) and data analysis methods; 6. Wrapping up and Self-reflection; and 7. Conclusion.

Senior Group

Day 1 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) Introduce the latest advances of the Tin Ka Ping P.A.T.H.S. Project during the full implementation phase (2015-2016); b) Familiarize the teachers with the constructs and teaching units.	1. Introduce the Tin Ka Ping P.A.T.H.S. Project and the professional team; 2. Warm-up activities; 3. Introduce the training schedules of the Project; 4. Guide the participants how to use the updated teaching materials and other resources of Tin Ka Ping P.A.T.H.S. Project; 5. Introduce the Co-Walker Scheme; 6. Introduce the results of the first training program evaluation; 7. Lecture on the constructs of “Bonding (BO)” and the contents of units; 8. Lecture on the constructs of “Self-Efficacy (SE)” and the contents of units; 9. Lecture on the constructs of “Prosocial Involvement (PI)” and the contents of units; 10. Lecture on the constructs of “Social Competence (SC)” and the contents of units; and 11. Lecture on the constructs of “Self-Determination (SD)” and the contents of units.
Day 2 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) Offer opportunities for school delegates to share their implementation experiences and teaching plans; and b) Familiarize the participants with teaching methodology of the Tin Ka Ping P.A.T.H.S. Project;	1. Lesson demonstration by school teachers from participating schools; 2. Group discussion and Q&A session; 3. Wrapping up and Self-reflection.
Day 3 (6.5 hours)	
Themes and Objectives	Activities Conducted
a) Familiarize the teachers with the constructs and teaching units. b) Clarify participants’ questions on project implementation; and c) Familiarize the participants with the evaluation methods of Tin Ka Ping P.A.T.H.S. Project.	1. Warm-up activities; 2. Lecture on the constructs of “Prosocial Norms (PN)” and the contents of units; 3. Lecture on the constructs of “Moral Competence (MC)” and the contents of units; 4. Lecture on the constructs of “Prosocial Involvement (PI)” and the contents of units; 5. Interactive lecture on the evaluation instruments of the program (form A, form B, and weekly report) and data analysis methods; 6. Wrapping up and Self-reflection; and 7. Conclusion.

ACKNOWLEDGMENT

The preparation for this paper and the Tin Ka Ping P.A.T.H.S. Project are financially supported by Tin Ka Ping Foundation.

ABSTRACT

General education has become more important in higher education to nurture students' capacities in different domains for their thriving in an increasingly globalized world. Through qualitative evaluation based on descriptors and open-ended questions, the present study examined teachers' views and experiences of a new general education program "General University Requirements" (GUR) developed by The Hong Kong Polytechnic University (PolyU) when its undergraduate program was reformed from three to four years. Seventy-eight teachers teaching subjects in different GUR

* Corresponding Author's Email: daniel.shek@polyu.edu.hk.

components in Semester 1 of the 2014-2015 academic year completed the evaluation form. Results suggested that teachers had highly positive feelings and impressions of the subjects they taught. They perceived their subjects as helpful to students' development with respect to the five desired graduate attributes of PolyU. Teachers also identified important merits of and challenges to the GUR curriculum.

Keywords: general education, higher education, Hong Kong, qualitative evaluation, teachers

INTRODUCTION

General education has a long history in educational philosophy and practices. Its idea stems from the idea of liberal education in Ancient Greek and Roman times. In that time, liberal education was a privilege of upper class with an aim of creating freemen through a curriculum of seven liberal arts: grammar, logic, rhetoric, arithmetic, geometry, astronomy, and music [1]. In modern universities, general education has become a comprehensive education for all university students. It inherits the essential idea of ancient liberal education that aims to nurture rounded persons and effective citizens through developing common knowledge and intellectual skills such as higher-order thinking and effective communication [1].

Several core concepts and related curricular models have been developed during the development of general education. Robert Maynard Hutchins (1899-1977) [2], the former president of the University of Chicago, argued that the aim of general education should be the cultivation of intellectual virtues and habits. These intellectual virtues were contained in classical books and formed the core of the intellectual heritage of Western civilization. Therefore, through this cultivation, general education contributed to the unity and continuity of Western society. In other words, general education helped "to connect man with man, to connect the present with the past, and to advance the thinking of the race" [2]. Based on this concept, the great book model of general education curriculum was developed. The model consisted of learning of great books in Western civilization together with some fundamental subjects on thinking, communication and mathematics [3]. Similarly, the Harvard Committee on General Education in 1945 [4] proposed that the broad social aim of general education was for the unity and continuity of Western cultural heritage and Western societies. However, they claimed that the curricular mean for this education was one that consisted of learning of three knowledge areas including natural science, social science and humanities, and stressed cultivation of five traits of mind including effective thinking, communication, judgment making, and value discrimination. Related to this concept, the scholarly discipline model of general education was developed. This model introduced students to major disciplines of college that were regarded as the best storage of the human intellectual heritage [3].

The above concepts of general education were classic. However, they were criticized by other modern educators such as John Dewey (1859-1952) for their separation of theory and practice and their neglect of the role of student experience in education [5]. Dewey [6] argued that education should be built on or should take into account students' experience and genuine development of thinking was based on reflection on experiences. Therefore, Dewey [6] perceived education as a social and interactive process with the aim of having students learn to live as effective citizens and realize one's potentials rather than obtain pre-determined

knowledge. Related to Dewey's philosophy of education, the effective citizen model of general education was established. The aim of the model was to develop in students the values and skills for effective citizenship through studying issues concerning contemporary society [3]. Particularly, Dewey's ideas influence the development of experiential education and some new modes of curriculum such as service learning in contemporary general education programs.

With regard to the practice, general education has been promoted and implemented in higher education in many places in contemporary society. In the context of Hong Kong, in response to challenges of the globalized knowledge economy and civic construction of Hong Kong society after its return back to China, the University Grants Committee (UGC) of Hong Kong mandated a reform to undergraduate education of all public universities of Hong Kong. Commencing from the 2012-2013 academic year, the eight public universities of Hong Kong transformed their undergraduate programs from three to four years. As an integrated part of this reform, each university introduced a significant component of general education in its new four-year curriculum. The reform aimed "to strike a new balance between breadth and depth" [7] of students' learning and to put greater emphasis on the development of students' foundational and generic skills in higher education [7].

As a key player of the above reform, The Hong Kong Polytechnic University (PolyU) extended its undergraduate degree program from three to four years. In the new four-year curriculum, a general education component named "General university requirements" (GUR) was introduced. The GUR aims to develop students in five desired graduate attributes, including effective communication, critical thinking, innovative problem solving, lifelong learning, and ethical leadership. The curriculum is comprised of six major components: Freshman Seminar (FS, 3 credits), Leadership and Intrapersonal Development (LIPD, 3 credits), Language and Communication Requirements (LCR, 9-credit English and 3-credit Chinese subjects), Cluster Area Requirements (CAR, 12 credits), Service Learning (SL, 3 credits), and Healthy Lifestyle (HLS, non-credit-bearing). Active teaching and learning methods are incorporated in the teaching and learning of the GUR, including cooperative and experiential learning, writing practice, as well as other innovative teaching strategies. A brief summary of each curricular component is listed as below:

- FS: introduce students to their disciplines and potential majors, and develop higher-order thinking, entrepreneurship, and self-learning.
- LIPD: nurture inter- and intra-personal qualities that lead to effective and ethical leadership.
- LCR: develop language proficiencies in English and Chinese.
- CAR: expand intellectual horizons and develop reading and writing skills.
- SL: cultivate social responsibility, empathy and attitude of serving the others.
- HLS: develop healthy lifestyle through learning knowledge and theories, and sports skills training.

The structure of the GUR is comprehensive and active teaching and learning methods are adopted. Although it was assumed that such pedagogies are welcomed by students, scientific evaluation findings are needed. To understand the functioning and effectiveness of the GUR, systematic evaluation studies should be conducted. To this end, qualitative evaluation is one

good approach to understand the impact of GUR on students. Qualitative evaluation is commonly used in educational field. Through a variety of methods such as focus group, individual interview, open-ended written question, self-reflection, and others [8-10], qualitative evaluation investigates viewpoints of important stakeholders to provide in-depth information and develop a more context-based understanding of program implementation [11-13]. Qualitative methods might be particularly useful in educational evaluation since “there is no single determination of worth for any educational endeavor. Worth is complex and personal” and “part of an evaluator’s responsibility is to indicate who finds merit in what, and what criterial and standards they appear to exercise” [14].

Teachers are important stakeholders of general education programs. Therefore, to understand views of teachers and listen to the voices to teachers as major stakeholders are important. To understand teachers’ views of the GUR, qualitative evaluation based on teachers’ written responses to open-ended questions were conducted. Comparing with other qualitative evaluation methods such as focus group and individual interviews, collection of written responses has several unique features. First, this method is more cost-effective and resource-saving. Second, data gathered from written responses might be more logical and consistent in expression than data gathered from focus groups in which participants’ expression might be more impromptu and less thoughtful. Thirdly, some forms of written responses such as descriptors and short phrases could also be analyzed in a more quantified approach. Based on this, the present study examined teachers’ views and experiences of the GUR through their written responses collected from the qualitative evaluation forms to understand the implementation and effects of the GUR at PolyU.

METHODS

At the end of the first semester of the 2014-2015 academic year, a total of 128 staff members who were involved in teaching of subjects in different components of the GUR curriculum were invited to fill in an online qualitative evaluation form. These teaching staff was sampled mainly based on nomination of subject leaders and important teachers in different GUR components and direct invitation of teachers based on the list of some GUR components. By early February of 2015, 78 staff members had completed the online form, with a response rate of 60.94%. The numbers of participants in different GUR components were: FS (n = 8), LIPD (n = 12), English LCR (n = 10), Chinese LCR (n = 7), CAR (n = 19), SL (n = 11), and HLS (n = 11). Detailed information is shown in Table 1.

Instrument

The online qualitative evaluation form was developed by the authors. It was comprised of two major parts. The first part required staff members to use “three descriptors or short phrases” to describe their general impression and feelings about the GUR subjects they taught in the first semester of the 2014-2015 academic year. The second part consisted of two open-ended questions:

- Have you observed any changes in your students after studying the GUR subject you taught in this semester? If yes, please describe the changes.
- Have you encountered any difficulties or challenges in your teaching of the GUR subject in this semester? If yes, what might be the reason(s) for these difficulties or challenges?

Data Analysis

All the written responses collected from the online evaluation forms were input into an Excel file for analyses. For the analysis of descriptors, the unit of analysis was a meaningful unit instead of a mere statement. All the meaningful units were carefully read by a researcher. The researcher in the first step coded these units into four broad categories, namely “positive,” “negative,” “neutral” and “undecided.” Under each category, the meaningful units were further coded into different themes. For the analysis of teachers’ responses to each of the two open-ended questions, all teachers’ written responses were carefully read by a researcher for several times and were coded into different themes and subthemes. Furthermore, all codes were carefully checked to ensure their accuracy.

Table 1. Number of participants in teacher qualitative evaluation

Component of GUR Curriculum	Numbers of Teaching Staff Being Invited	Numbers of Teaching Staff Completing the Form
FS	17	8
LIPD	12	12
English LCR	10	10
Chinese LCR	9	7
CAR	50	19
SL	19	11
HLS	11	11
Total	128	78
Response Rate	60.94%	

Note. FS = Freshman Seminar, LIPD = Leadership and Intrapersonal Development, English LCR = English Language and Communication Requirements, Chinese LCR = Chinese Language and Communication Requirements, CAR = Cluster Area Requirements, SL = Service Learning, HLS = Healthy Lifestyle.

Table 2. Summary of descriptors/short phrases teachers used to describe their general impression and feelings towards the GUR subjects

Descriptors/Short Phrases	GUR Component							Total	%
	FS	LIPD	ELCR	CLCR	CAR	SL	HLS		
Positive	17	29	24	14	40	28	23	175	82.16
Neutral	1	3	0	2	1	9	0	16	7.51
Negative	1	1	2	5	4	3	2	18	8.45
Undecided	0	0	0	1	2	0	1	4	1.88
Total	19	33	26	22	47	40	26	213	100.00

RESULTS

The first question in the evaluation form asked the teachers to use three descriptors or short phrases to describe their general impression and feelings of the GUR subjects they taught. A total of 213 descriptors/short phrases were collected. Among these descriptors/short phrases, 175 (82.16%) were classified as positive descriptors, 16 (7.51%) were classified as neutral descriptors, and 18 (8.45%) were coded as negative descriptors. Detailed information about classification of descriptors/short phrases in total and by each GUR component is shown in Table 2. The 175 positive descriptors/short phrases were further coded into six themes, namely “Impact of Subject Teaching on Teachers,” “Teachers’ Perceived Benefits of Their Subjects and Related Teaching to Students,” “Teachers’ Perceived Merits of GUR Subjects,” “Teachers’ Relationship with Students,” “Teachers’ Perceived Engagement of Students,” and “Others.” Table 3 provides a detailed summary of the positive descriptors/short phrases under each theme and subtheme.

Table 3. Summary of positive descriptors/short phrases given by teachers to describe their general impression and feelings of the GUR subjects

Under the theme “Impact of Subject Teaching on Teachers”, 63 (36.00%) descriptors were collected. These descriptors were further coded into five subthemes, namely “sense of achievement” (n = 23), “sense of satisfaction” (n = 11), “enjoyable” (n = 6), “rewarding” (n = 5), and “others” (n = 18). This indicated that at least more than one third of the teachers had perceived benefits from their teaching of GUR subjects, particularly that they developed sense of achievement and satisfaction, and felt enjoyable and rewarding from their teaching experience.

Under the theme “Teachers’ Perceived Benefits of Their Subjects and Related Teaching to Students”, 53 (30.29%) descriptors/short phrases were collected. These descriptors/short phrases were further coded into five subthemes: general benefits, character building, multi-disciplinary learning, competence, and others. Notably, in the subtheme “competence,” six major competences in alignment with the five desired graduate attributes of PolyU were identified, including effective communication, critical thinking, problem solving, lifelong learning, self-understanding, and social responsibility. Under the subtheme “character building”, teachers perceived their GUR teaching as beneficial to resilience, confidence and creativity of students.

Under the theme “Teachers’ Perceived Merits of Curriculum”, 38 (21.71%) descriptors/short phrases were collected and further coded into three subthemes: content, method, and general and others. In the subtheme “content”, descriptors/short phrases such as “rich content,” “sufficient content,” and “practical” were collected. The subtheme “method” included descriptors such as “engaging teaching methodology,” “hands-on,” “interactive” and “student-oriented”. Some teachers also perceived their subjects as “impressive,” “influential,” “insightful,” and “invigorating” in general. Finally, descriptors under the themes “Teachers’ Relationship with Students” and “Teachers’ Perceived Engagement of Students” suggested

that some teachers established close relationship with students through their teaching of GUR subjects and some perceived their subjects as highly motivating and engaging.

Table 4. Summary of neutral and negative descriptors/short phrases teachers used to describe their general impression and feelings towards the GUR subjects

Lack of a sense of achievement because the comment from OGUR on HLS is negative but without sound evidence							1	1
Many arguments among colleagues on the evaluation method of different stage of HLS							1	1
Under-estimated and misunderstood by both students and other faculty members		1						1
Gain a superficial understanding through cursory observation (from subject credit and content)				1				1
Helpless (from student composition and course scheduling)				1				1
Total	1	1	2	5	4	3	2	18

In addition to the positive descriptors presented above, there were also 16 (7.51%) and 18 (8.45%) descriptors/short phrases that were classified into “Neutral” and “Negative” categories, respectively (see Table 4). Among the neutral descriptors, some indicated a feeling of “challenging” in teachers regarding to their GUR teaching (such as “a challenge to the teaching team”, “somewhat challenging”, and “meet the challenge”). Some indicated teachers’ perceived importance of motivating students in their subjects (such as “motivation of students is very important”; “keeping the interest of students is important”). The negative descriptors were much diversified. Some indicated teachers’ heavy workload in teaching SL and Chinese LCR subjects. Some suggested that few teachers lacked a sense of achievement through their teaching of GUR subjects, particularly the Chinese LCR subjects.

Teachers’ Observed Changes in Their Students after Studying Their Subjects

For the first open-ended question “have you observed any changes in your students after studying the GUR subject you taught in this semester?” 90 meaningful responses were collected. The detailed information is presented in Table 5. Among these responses, 83 (92.22%) were classified as positive responses. The positive responses were further coded into four themes, namely “Desired Graduate Attributes of PolyU,” “Intended Learning Outcomes of GUR Components,” “Broadening Knowledge/Horizon”, and “Others.” Remarkably, the theme “Desired Graduate Attributes of PolyU” was comprised of 47 (56.63%) responses, and these responses were further coded into five subthemes including effective communication, ethical leadership, critical thinking, problem solving, and lifelong learning. The theme “Intended Learning Outcomes of GUR Components” included 17 (18.89%) responses. These responses were further categorized into the intended learning outcomes of four GUR components including HLS, FS, SL, and LIPD. These findings indicated that teachers perceived a general alignment of their GUR subjects with the desired graduate attributes of PolyU and with their intended learning outcomes.

Specifically, among the 47 responses in the theme “Desired Graduate Attributes of PolyU,” 20 responses were related to the competence of effective communication. A detailed view of these responses revealed that teachers teaching different GUR subjects, particularly the subjects in LCR component, perceived that their students had become more confident in both oral and written communication through studying ELCR and CLCR subjects. The following written responses of teachers help to illustrate this benefit:

- “Some students were shy to share their ideas in front of their classmates. But they became more confident as the semester progressed. They learned to communicate well with their groupmates and applied different problem solving skills in the preparation of their presentation.”
- “Absolutely. I have seen some dramatic and very positive changes not just in students’ approach to academic research and writing, but also in their understanding of research ethics, the importance of developing effective communication skills, becoming confident speakers and effective presenters.”

The CAR and LIPD teachers also perceived students' improvements in their understanding of leadership and problem-solving skills after studying the related subjects, as illustrated by the following written responses:

- “Students become more reflective and mature. They started to realize that self-leadership is the first step for leading other people and they were willing to apply the knowledge and strategies learned in this subject (a CAR subject on service leadership) in their future university life.”
- “At the beginning of the semester, the students were quite passive in problem solving, no matter for the problems developed from class activities or the problem in group projects. ... [But] they became more mature in handling the conflicts among their group-mates after studying ‘relationship building, team building and conflict management’ and ‘social competence.’ At first, they might think the attribute of ‘social competence’ was a bit abstract to them. When they faced real and contextual problems and they could be able to apply the knowledge into the practice, they became clear about the attribute.”

With regard to the theme “Intended Learning Outcomes of GUR Components,” teachers teaching FS subjects in different faculties/schools noted that their FS subjects increased students' knowledge about their broad disciplines and related professions, as well as students' appreciation of their majors. Teachers teaching SL subjects observed an increase in empathy and social understanding of their students. Teachers wrote that through their subjects, students “become more mature and some develop a compassionate heart for the needy,” and “have developed a better understanding towards diversity.” These improvements in students can be further illustrated by the following responses of teachers:

- “Students from different disciplines and backgrounds can work together on a group project (in a FS subject). Each of them contributed to the project by employing their different backgrounds. It is a great subject as it helps the students to understand more about the construction industry and the responsibility of different professions.”
- “Students have developed a deeper appreciation to their chosen disciplines. They are more confident in tackling problems and issues pertaining to the study, exploration, and practice of their own disciplines.”

Difficulties/Challenges Teachers Encountered in Their Teaching of GUR Subjects

For the second question “Have you encountered any difficulties or challenges in your teaching of the GUR subject in this semester?” 56 meaningful responses were collected. Detailed information is presented in Table 6. Among the 56 responses, 11 (19.64%) indicated no challenge and problem encountered in teaching. The remaining 45 responses were coded into three themes: “Teaching and Learning,” “Course Design and Scheduling,” and “Others.” Around a half of the responses ($n = 26$, 46.43%) were coded under the theme “Teaching and Learning.” Several major challenges were identified under this theme, including student motivation and interests, teaching students from a variety of disciplines and with great variety of language proficiency, and students’ heavy workload. For example, one challenge expressed by the teachers was the lower motivation and engagement of some students in studying GUR subjects. Teachers perceived that students’ lower motivation might be due to their utilitarian mindset, heavy workload in undergraduate study and less knowledge about general education and the GUR. Meanwhile, some teachers perceived that it was difficult to teach students from different disciplines.

DISCUSSION

Through qualitative methods based on descriptors and open-ended questions, this study investigated views and experiences of teachers in a new general education program “General University Requirements” (GUR) which was an integral part of the new four-year undergraduate curriculum of PolyU. Several major observations could be made from the findings.

Firstly, the teachers gained positive feelings in their teaching. As indicated by the descriptors/short phrases given by the teachers, a lot of teachers developed a sense of achievement and satisfaction during their teaching. Some also felt rewarding and enjoyable. Teachers’ positive feelings were much important for the implementation and success of the GUR curriculum. A sense of achievement and satisfaction can generate high commitment to teaching as research indicated that a lack of job satisfaction was associated with serious withdrawing behavior of teachers and a sense of low achievement might lead to apathetic attitudes of teachers towards their teaching [15]. Particularly, in modern universities, the research-directed and specialized education dominated culture heavily undermined faculty’s devotion to teaching in general education [3, 16]. In this circumstance, a general education program that can promote teachers’ positive feelings could be regarded as successful and these positive feelings may further sustain and promote teachers’ good teaching.

Secondly, teachers perceived that the GUR curriculum benefitted the all-round development of students, particularly with respect to the desired graduate attributes of PolyU. The most significant impact was on communication skills. There might be three possible reasons for this learning outcome of the GUR. The first reason was the positive effects of LCR subjects that were specially designed to improve students’ language and communication skills. The second reason was the positive effects of the active and cooperative teaching and learning methods that were adopted in different GUR subjects, as identified from teachers’ responses. This was supported by the literature that cooperative learning was effective in promoting communication skills in adolescents and university students [17-19]. Students’ improvement in oral and written communication was also identified through active learning strategies [20]. The third reason was that students’ improvement in communication skills might be more easily observed by teachers in class than other attributes.

Thirdly, findings from the descriptors suggested some merits of the GUR curriculum, including rich and practical subject content, active and interactive pedagogy, as well as a close teacher-student bond. This is basically in line with the studies suggesting that good general education program might create community through collaborative learning and evaluating students’ learning through active experiences [21]. Fourthly, findings suggested several possibly pivotal challenges in implementation and teaching of general education. One critical challenge was the lower motivation of some students in studying general education subjects. This has been identified by the existing literature. Zhang’s [22] study indicated that one major challenge to teaching in general education in Chinese universities was how to arouse students’ motivation in learning these subjects in an environment in which undergraduates’ studies were dominated by specialized education. In universities in Hong Kong, students’ motivation in learning in general education might also be lower under the influence of the previous British model of undergraduate education [23] and the utilitarian philosophy of Chinese education. To promote students’ motivation and interests in learning

general education, two measures might be considered. One is to strengthen students' understanding of rationales of general education through all kinds of channels. Another is to incorporate more active and engaging teaching and learning methods in curriculum design to foster students' active and deep-level learning [24]. The second major challenge was students' increased study load under the structure of new four-year curriculum. This might diminish their engagement in study of GUR subjects. To tackle this problem, the university needs to reevaluate students' whole workload in the four-year curriculum and to take appropriate action to adjust students' workload.

The present study had three limitations. Firstly, although the use of descriptors could quickly gather teachers' general feelings and impressions, and could be analyzed in a more quantified way, this approach is limited when obtaining in-depth information about teachers' views. For example, in this study, few teachers used descriptors such as "disappointed" and "challenging" to describe their general feelings about the GUR subjects they taught. It would be hard to know in detail these feelings of teachers. Also, many teachers used descriptor "a sense of achievement" to describe their feelings. However, these descriptors could not reveal what achievement and in what context it was developed. Therefore, to enrich understanding of teachers' views, other qualitative studies such as focus group and individual interview should also be performed. For example, the use of repertory grid test may be helpful [25]. Secondly, although teachers were important observers of students' study and changes, some changes of students could not be easily observed by teachers in a short time such as improvements in critical thinking and ethical leadership. To gain a solidier understanding of the effects of the GUR, the method of objective outcome evaluation using validated instruments should be conducted to assess students' longitudinal changes during their studies of the GUR. Thirdly, to increase the trustworthy of the data collected from the teachers, views of other important stakeholders such as students could also be investigated.

Despite these limitations, the findings from the present study indicated a smooth implementation of the GUR curriculum and its positive effects on students' holistic development based on teachers' perspectives.

ACKNOWLEDGMENT

The authors thank The Hong Kong Polytechnic University for providing financial support via the Teaching Development Grant in conducting the GUR evaluation study.

Chapter 32

CONDOM USE, ALCOHOL, AND ALCOHOL-RELATED PERSONALITY CHANGES: A VIEW FROM RUSSIA

*Sergei V. Jargin**

People's Friendship University of Russia, Moscow, Russia

ABSTRACT

Abortion rate in the former Soviet Union was reported to be the highest in the world, which was caused by insufficient availability of modern contraception and frequent non-use of condoms. Alcohol abuse and heavy binge drinking were generally perceived as factors contributing to the non-use of condoms. The association between alcohol abuse and high-risk sexual behavior is explainable within the scope of the alcohol myopia theory, according to which, alcohol reduces the cognitive capacity and causes people to focus on the cues that are most salient in the environment. The prevailing opinion in the literature is that heavy binge drinking and alcohol consumption at sexual relations are risk factors for the non-use of condoms. Moreover, the irresponsible behavior is apparently favored by slowly progressive personality changes developing under the influence of chronic alcohol abuse and heavy binge drinking.

Keywords: condoms, alcohol, alcohol-related dementia, sexually transmitted infection

INTRODUCTION

The abortion rate in the former Soviet Union has been reported to be the highest in the world [1], which was obviously caused not only by insufficient availability of modern contraception, but also by irresponsible behavior expressed by non-use of condoms. There is evidence that the abortion rate in Russia has declined dramatically during the last decade [2] and the heavy binge drinking seems to be declining as well [3, 4]. Current trends in abortion and contraception are beyond the scope of this review, which is trying to analyze

* Corresponding Author's Email: sjargin@mail.ru.

psychological aspects of condom use in relation to the alcohol consumption. According to our observations from the Soviet past, individual carelessness acted in some cases synergistically with the alcohol abuse resulting e.g., in neglectful sabotage of the withdrawal method of contraception [5]. Condoms were of poor quality and imported ones were scarce, while Soviet-made condoms were notoriously thick and, at the same time, tore easily. Of oral contraceptives, mainly infecundin and bisecurin (both produced in Hungary), were known in the 1980s and they required prescription and were used infrequently. An unofficial directive from the late 1940s to enhance fertility was apparently behind it, effectuating e.g., poor quality and limited availability of contraceptive appliances, prohibition of abortions till 1955, as well as certain behavioral stereotypes.

ALCOHOL AND SEXUAL RISK BEHAVIOR

The association between alcohol consumption and high-risk sexual behavior is explainable within the scope of the alcohol myopia theory [6, 7]. According to this theory, alcohol reduces cognitive capacity and causes people to focus on the cues that are most salient in the environment. Less salient cues require additional cognitive resources to process and are, therefore, less likely to be acted upon by an inebriated person [7]. Furthermore, the effect of alcohol on cognition is supposed to be linear: the more intoxicated a person is, the more pronounced the “myopia” becomes [8]. In sexual encounters, the most salient cues are usually those that involve immediate sexual engagement. More distant cues, such as a suspicion that the partner could be infected by a sexually transmitted infection (STI), are less salient. Therefore, when intoxicated by alcohol, the ability to consider less salient cues decreases and the protective behavior is less likely to be enacted [7]. Interestingly, according to a study performed in women, alcohol directly increased the risk through weaker future condom use intentions, but indirectly decreased the risk for women who are higher in condom use self-efficacy through stronger in-the-moment condom negotiation intentions [9]. This is understandable as alcohol might help to overcome communicative barriers enabling a momentarily more decisive condom negotiation. According to other research, people intoxicated with alcohol reported more prudent intentions than sober ones, provided that the most salient features of the situation emphasized the risks of unprotected sex [10], which is also in accordance with the alcohol myopia theory.

The role of alcohol in the safer sex decision making is discussed in the literature, the prevailing opinion being that heavy binge drinking and alcohol consumption at sexual relations are risk factors for non-use of condoms [11-17]. Furthermore, heavy binge drinking is associated with severe hangover sometimes accompanied by a transitory depression, while depressive symptoms were demonstrated to be associated with unprotected sex [18]. In particular, alcohol use was reported to be significantly associated with unprotected sex among people with HIV/AIDS [19]. Moreover, sexual violence often coincides with heavy alcohol use [20, 21]; whereas use of condoms within the context of violence would be less probable than on average [22]. The topic alcohol and condom use is, however, not without controversy: drinking was reported to be inconsistently related to protective behaviors such as the condom use among college students and youth [23]. Some researchers did not find any relation between drinking and lower condom use [24]. There is an opinion that people who use

condoms when they are sober would use them also when they are drinking, while those who fail to use condoms when drinking probably also fail to use them when sober. However, empirical exceptions from this rule are recognized by the same researchers [7]. In the author's opinion, sexual behavior largely depends on personal features; but, taken on average, heavy binge drinking and alcohol consumption at sexual relations are risk factors for the non-use of condoms.

PERSONALITY TRAITS

Among various personality traits, the non-use of condoms is apparently favored by those developing as a result of prolonged alcohol abuse in relation to the deficit in frontal inhibitory control and cognitive impairment [25] i.e., beginning alcohol-related dementia, the latter overlapping with such entities as the frontal or prefrontal syndrome [25, 27] and organic personality disorder [28]. The cortical changes and symptoms of alcohol-related dementia are partly similar to those found in frontotemporal dementia [29], also known as Pick's disease [30]; demarcation of these conditions is beyond the scope of this review. It should be mentioned that the term "alcoholic dementia" used in Russia does not exactly correspond to the internationally used term "alcohol-related dementia" as nutritional deficiency, brain injury, e.g., old subdural hematoma [31], and chronic diseases, can play a role in its pathogenesis [32], especially, if chronic diseases are not adequately treated. Frontal lobe dysfunction is regarded to be a hallmark of alcohol dependence [33]. Among manifestations are social and personal neglect, lack of insight [29], faulty foresight, disinhibition in the affective and emotional sphere, disinhibition of instinctual behavior [26], impulsivity i.e., inability to forego small, immediate rewards for larger, delayed rewards [34]. This means that not only an immediate impact of alcohol intoxication is conducive to the non-use of condoms but also slowly progressive personality changes under the influence of chronic alcohol misuse, the heavy binge drinking in particular. Poor quality of alcoholic beverages i.e., other substances than ethanol may be of importance in this connection [35], which should become a topic of further toxicological research.

SURVEYS

It should be commented that data on alcohol consumption and use of condoms obtained by means of surveys in Russia are of limited validity. Many studies on the alcohol consumption in Russia e.g., [36-38] and other countries have been based on surveys. However, there are international differences in this regard. Evaluating results of surveys and opinion polls, it should be taken into account that these research tools have been largely discredited in Russia since the 1990s by means of widespread obtrusive solicitations to partake in different surveys, often asking for private information: in the streets, per telephone, and also by agents coming to private homes. Accordingly, people in Russia are generally "sick and tired" of questionnaires; and many of them tend to conceal their true opinions [39]. This pertains to opinion polls and scientific surveys, both being discredited. The tendency to discredit surveys and opinion polls can be seen as a continuation of the Soviet-time attitude,

when the “frame of mind of the working population” was monitored but the data were kept secret or published after a trimming to adjust them to the official ideology [39]. Answers to the questionnaires can be biased, especially in regard to such delicate topics as alcohol consumption and condom use. The statements with references to foreign literature, e.g., that the “earlier research has suggested that, at least for drinking behavior, reports (by adolescents) can be regarded as being generally valid” [36] are in fact not supported by the references to studies from West Europe [40], where the attitude to the surveys is probably more responsible.

Here follows an example. The study [36] was based on a survey carried out among adolescents 13-17 years old. “In terms of sexual behaviour, there was no difference in the odds ratios between binge drinking and non-binge drinking girls and boys for non-condom use during last sex” [36]. In other words, the adolescent binge drinking was reported to be not associated with “non-condom use during last sex”. However, it can be reasonably assumed that the study subjects answered the question “The last time you had sex did you or your partner use a condom?” [36] with “yes” without pondering that it is a research having potential significance for the public health etc. Respondents were probably unwilling to admit to the disapproved practices such as non-use of condoms.

CONCLUSION

In conclusion, according to the literature and our observations since the 1970s [3, 5], heavy binge drinking and alcohol consumption at sexual relations are risk factors for non-use of condoms and hence of STI and unintended pregnancy. Moreover, the chronic alcohol abuse and heavy binge drinking are apparently associated with progressive personality changes conducive to the irresponsible behavior including non-use of condoms.

ABSTRACT

The study examined the prevalence of suicidal ideation and associated factors among students in Uruguay in grades 2 CB, 3 CB and 1BD in 2012 in a Global School-based Student Health Survey. Both bi-variate and multi-variate logistic regression analyses at 95% confidence level were conducted to assess associations between relevant predictor variables and suicidal ideation within the previous twelve months. Out of a total of 3,524 students who participated in the survey, 3,480 of them responded to the question on suicidal ideation among other questions. Overall, 12.3% of the students reported having had suicidal ideation in the previous 12 months (7.2% among males and 16.6% among females). Being anxious, lonely, having no close friends, bullied, physically attacked or involved in a physical fight just like smoking cigarettes or marijuana, alcohol consumption and abuse were all significantly associated with suicidal ideation. Having parents or guardians who did not understand the adolescent's problems and worries was also significantly associated with suicidal ideation. Interventions that address issues of violence against students, fighting with peers, initiation of smoking, alcohol and illicit drug use and those that encourage supportive roles of parents may reduce the risk of suicidal ideation.

Keywords: suicidal ideation, prevalence, associated factors, Uruguay

INTRODUCTION

Suicide is a global public concern as more than 800,000 people commit it every year and for every suicide there are many more who attempt it [1]. A prior suicide attempt is the single most important risk factor for suicide in the general population [1]. In 2012, suicide was the second leading cause of death among 15-29 year olds worldwide and occurs throughout the life span [1, 2]. The Global Burden of Disease Study in 2004 estimated that suicide contributes to 6% of all deaths among young people aged 10-24 years worldwide [3]. Suicide does not just occur in high-income countries, but is a global phenomenon in all regions of the world [1]. Notably, in 2012, 75% of global suicides occurred in low and middle income countries [1, 2]. Previously, suicide rates were found to be low in Latin American countries, but that has been expected to change [4, 5]. In Uruguay, literature on suicide or suicidal ideation is scarce [6, 7]. Suicide is preventable with timely, evidence-based and often low-cost interventions [1, 8].

Suicidal ideation is both a strong risk factor and a stage in the suicidal process from planning to committing suicide [9, 10]. Although not all suicidal ideation materialize into suicide attempts or suicide, it is the first step on to the path to suicide [11]. A 60% rate of transition has been observed from suicidal ideation to first suicide attempt within the first year of ideation on-set [12]. Hence, prevention of suicidal ideation may in turn prevent suicide. To date, several environmental, psychosocial and behavioural factors have been associated with suicidal ideation, suicidal attempts and suicide. Physical, sexual and emotional abuses have also been associated with adolescent suicidal ideation and attempts [8, 12, 13].

In Brazil, the prevalence of suicidal ideation was observed to be 14.0% and was associated with violent behaviour, smoking and alcohol consumption [14]. Bullying of students was found to be common in Chile and was associated with suicidal ideation [14]. Family problems, social pressure, economic struggle, racism and violence introduce constant emotional stresses and challenges among Peruvian adolescents [14]. In addition, a strong association was observed between peer victimization and emotional, and mental stress among adolescents in Peru [14] may lead to having suicidal thoughts. The prevalence of suicidal ideation and its associated factors among junior high school students in Uruguay is unknown. Therefore, the objective of this study was to estimate the prevalence of suicidal ideation as well as identify factors associated with this phenomenon.

METHODS

The study was conducted in Uruguay (see Figure 1), a country on the east coast of South America, and south of Brazil and east of Argentina. The country consists of a low, rolling plain in the south and a low plateau in the north. Uruguay is a high-income country with a gross national income per capita of US\$ 16,810 in 2014 and there is no extreme poverty [15].

Figure 1. Uruguay and its neighbouring countries.

The Global School based Health Survey (GSHS) was developed by the World Health Organization (WHO) in collaboration with UNICEF, UNESCO and UNAIDS with technical assistance from Centers for Diseases Control and Prevention, Atlanta, Georgia, United States with the aim of providing data on health and social behaviours among school-going adolescent students. This paper presents results of a secondary analysis of the data obtained from the GSHS conducted in 2012 students in Uruguay. The survey measured alcohol use; dietary behaviours; drug use; hygiene; mental health; physical activity; protective factors; sexual behaviours; tobacco use; violence and unintentional injury.

The Uruguay GSHS used a two-stage cluster sampling design, in which in the first stage, schools were selected with probability proportional to enrolment size. In the second stage, classes were randomly selected and all students in selected classes were eligible to participate. The school response rate was 100%, the student response rate was 77% and the overall response rate was 77%. A total of 3,524 students participated in this survey. Students self-reported their responses to each question on a computer-scannable answer sheet.

Variables that were used for our analysis included socio-demographic characteristics, having seriously considered attempting suicide, smoking, loneliness, parental understanding, involvement in a fight, truancy, anxiety, close friendship and food security. Assessments of associations were conducted using both bi-variate and multivariate logistic regression analyses with 95% confidence intervals using SPSS Version 16.0.0.

RESULTS

A total of 3,524 students participated in the Uruguay 2012 Global School-based Students Health Survey, of which 46.0% were males. Most of the students were either of age 14 years (30.1%) or 15 years (30.2%). About 1 in 4 students (26.7%) missed classes or school without permission. Overall, 18.6% of students reported being bullied and 16.0% were physically attacked. Significantly, more males (38.4%) than females (17.2%) were involved in a physical fight ($p < 0.001$). Altogether, 13.1% of the students reported that they smoked cigarettes 30 days prior to the survey, and 12.7% reported that they smoked marijuana in their lifetime. About half (48.6%) of both males and females consumed alcohol, while 28.9% abused it. Overall, 60.9% of students indicated that their parents or guardians understood their problems and worries. The prevalence of suicidal ideation was 12.3% with significantly more female students (16.6%) than male students (7.2%) ever seriously considered attempting suicide ($p < 0.001$). These results are shown in Table 1.

Table 2 shows factors that were associated with suicidal ideation. All the factors that were considered in the analysis were significantly associated with suicidal ideation in bivariate analyses. However, in multivariate analysis, food security was no longer significantly associated with suicidal ideation.

Compared to students who were aged 16 years or older, students of age less than 14 years (AOR = 0.77, 95% CI [0.73, 0.81]) and of age 15 years (AOR = 0.95, 95% CI [0.91, 0.99]) were less likely to seriously consider attempting suicide; while students of age 14 years (AOR = 1.23, 95% CI [1.18, 1.28]) were more likely to have suicidal ideation.

Male students were 41% (AOR=0.59, 95% CI [0.58, 0.61]) less likely to have suicidal ideation than female students.

In relation to anxiety and loneliness, students who were worried about something that they could not sleep at night were 75% (AOR = 1.75, 95% CI [1.68, 1.81]) more likely to have suicidal ideation than students who were not anxious. Meanwhile, students who felt lonely were 2.03 (95% CI [1.96, 2.09]) times more likely to have suicidal ideation than students who did not.

Students who did not have close friends were more likely to have suicidal ideation than those who had close friends (AOR = 1.11, 95% CI [1.04, 1.18]). Compared to students who did not miss classes or school without permission, students who were truant were 15% (AOR = 1.15, 95% CI [1.12, 1.18]) more likely to seriously consider attempting suicide.

Being bullied, physically attacked and involvement in a physical fight were significantly associated with suicidal ideation. Students who were bullied were 39% (AOR = 1.39, 95% CI [1.35, 1.43]) more likely to have suicidal ideation compared to students who were not bullied. Compared to students who were not physically attacked, those who were attacked were 1.38 (95% CI [1.35, 1.42]) times more likely to have suicidal ideation. Students who

were involved in a physical fight were 14% (AOR = 1.14, 95% CI [1.11, 1.17]) more likely to have suicidal ideation compared to those who were not in a physical fight.

No	1	1

Smoking (cigarettes (AOR = 1.61, 95% CI [1.56, 1.66]); marijuana (AOR = 1.08, 95% CI [1.04, 1.12]) were significantly associated with suicidal ideation. Students who consumed alcohol were 22% (AOR = 1.22, 95% CI [1.19, 1.25]) more likely to have suicidal ideation compared to students who did not consume alcohol. Meanwhile, students who abused alcohol were 1.16 (95% CI [1.13, 1.19]) times more likely to have suicidal ideation compared to those who did not abuse alcohol.

Students who reported that their parents or guardians understood their problems and worries were 19% (AOR = 0.81, 95% CI [0.79, 0.83]) less likely to seriously consider attempting suicide.

DISCUSSION

In this study, the prevalence of suicidal ideation was 12.3% which is low when comparing with the result from China [16]. The prevalence of suicidal ideation among males was about half that among females (7.2% vs 16.6%). This finding was also observed in a similar study done elsewhere [14]. It is, however, surprising that this is the case, as globally, actual suicide deaths occur more among males than females [16].

With regard to age, the study found that there was an association between age group and suicidal ideation which indicates some unequal risk of suicidal ideation among different aged adolescents. Students who were less than 14 years of age and those that were 15 years of age were less likely to consider attempting suicide. This finding contradicts the findings in the Peru study which did not find any association between age and suicidal ideation and therefore reported an equal risk of suicidal ideation among different aged adolescents [14, 17]. The study by Muula et al. found that adolescents who were less than 14 years of age were more likely to consider committing suicide [11]. This finding and our finding are different from the findings of Liu et. al. who found increasing age to be correlated with suicidal behaviour [16]. We are, however, unable to offer a plausible explanation as why students who were 14 years of age (compared to other age groups in the study) were less likely to have suicidal ideation because in most cases, it is the slightly older adolescents who would think of committing suicide more than the younger ones. Muula et al. in their paper explain that younger children may not have developed problem solving skills and as such they are more likely to consider committing suicide than the older ones [11].

In this study, being anxious, lonely, having no close friends, missing classes or school without permission were all associated with suicidal ideation. Being bullied, physically attacked and involvement in a physical fight were all significantly associated with suicidal ideation. Students who were bullied were 39% more likely to consider attempting suicide and those involved in physical fights were 14% more likely to have suicidal ideation. This indicates that adolescent violence and bullying is common in Uruguay. In a similar study among Brazilian adolescents, being involved in a physical fight was associated with a higher rate of suicidal ideation [14]. Similarly, being bullied has been seen as an important risk factor of suicidal ideation in study findings in other countries [11, 14]. This indicates that physical and emotional violence against adolescents is related to suicidal ideation.

The study revealed a significant association between smoking and suicidal ideation. Similarly, another study also observed cigarette smoking as a risk factor for suicidal ideation [14]. Alcohol consumption and abuse were both associated with suicidal ideation. This association has also been reported in a similar study [11]. Students who consumed alcohol were 22% more likely to consider attempting suicide. We therefore assume that preventing initiation of smoking, alcohol consumption among adolescents in Uruguay may in turn prevent suicide.

We observed that students whose parents or guardians understood their problems and worries were 19% less likely to consider committing suicide. A similar finding has been reported Randall et al. [18]. Poor parenting may cause physical and emotional stress as well as impaired social and cognitive development [19-21].

In conclusion, although the prevalence of suicidal ideation was found to be relatively low, a number of factors were significantly associated with this phenomenon among the participants in the study area. We propose that preventive interventions measures of suicidal behaviours that have been found to be significantly associated with suicidal ideation be put in place. These should focus on prevention of violence against adolescents, encouraging peer relationships and controlling health risk behaviours, particularly initiation of smoking, alcohol use and abuse

ACKNOWLEDGMENTS

The authors wish to express their appreciation and gratitude to the World Health Organization (WHO) and Centres for Disease Control (CDC) for making the data available for analysis.

ABSTRACT

Suicide in adolescents has become a major health concern for many countries especially African countries where conditions of living are generally poor. However, there is paucity of data regarding the prevalence of suicidal ideation and its correlates in most African countries including Ghana where the vice is on the rise. The purpose of this study was to determine the prevalence and correlates of suicidal ideation among adolescents in grades SS1-3 in Ghana. Analyses are based on the 2012 Global School-Based student Health Survey (GSHS) conducted in Ghana. Logistic regression analyses were conducted to determine associations between the factors (i.e., food security, current alcohol use, bullying victimization, loneliness, anxiety, having no close friends, missed school, parental understanding, smoking, physical fights, physical attacks) and suicidal ideation for all students that participated in the study. The prevalence rate for suicidal ideation among adolescents (N = 1648) attending schools was 20%. Significantly (p < 0.001) more females (21.7%) contemplated on committing suicide than males (19.2%). Being of age <14 or 15 years and male gender were protective against suicidal ideation.

* Corresponding Author's Email: chitembusha@yahoo.com.

No food security, current alcohol abuse, bullying victimization, loneliness, anxiety, having no close friends, truancy, parental understanding, smoking, physical fights, and physical attacks, were all found to be risk factors of suicidal ideation. The prevalence of suicidal ideation in Ghana was high and could lead to high suicide rates. Therefore, there is an urgent need for additional studies in this area to greatly up regulate suicide prevention efforts.

Keywords: suicidal ideation, adolescents, risk factors, Ghana

INTRODUCTION

Suicidal ideation is a thought about how to kill oneself, which can range from a detailed plan to a feeling consideration and does not include the final act of killing oneself [1]. Approximately one million people die from suicide every year; which translates in a “global” mortality rate of 16 per 100,000, or one death per 40 seconds [1]. Pompili et al. [2] reported that suicide is now a major health concern for many countries. Across the world, it is estimated that 71,000 adolescents die due to suicide and 40 times as many adolescents attempt to commit suicide, a fact that categorises suicide as the third leading cause of death among adolescents [1].

In Ghana, the Ghana Statistical Service’s report of 2013 shows 18,938 deaths recorded and categorised as accidents, homicide, or suicide within 12 months preceding the census which was conducted in 2010 [3]. It should be stated that official statistics on adolescent suicide in Ghana is lacking. The data that seems to be available concerns deaths amounting to 6467 adolescents categorised under accidents, violence, homicide or suicide [3]. A study conducted by Adinkrah [4] using police recorded information, shows 9.1% suicides among adolescents. Although this information on suicides appears to be unreliable, it can act as an indication to the implication that, adolescent suicide cases are on the rise in Ghana [5]. More reliable data were determined in the Global School-based Student Health Survey (GSHS) conducted in 2012 in Ghana, where 19.0% adolescents reported to have had suicidal thoughts in the previous 12 months [6]. In studies done elsewhere in Africa, the prevalence rates of suicide ideation have been found to be high [7, 8]. In order to reduce these prevalence rates, investigation of risk factors is cardinal.

The risk factors for suicidal ideation have been categorised as follows: psychiatric, biological, social, environmental and factors related to an individual’s life history [9]. The effects of these factors tend to vary according to countries. In a study conducted in 2015 by Quarshie et al. [10], on adolescent suicide in Ghana, five subthemes were used as key drivers in the motivation for this adolescent suicidal behaviours, these were; psychological factors, conflictual relationships, loss of significant other, poor school work, and socio-economic factors. However, there are differences in the prevalence of suicide ideation and factors associated to it across gender, race cultures and countries in the world [11].

There are few quantitative studies that have been conducted on the magnitude of suicide ideation among adolescents attending school in Ghana. Furthermore, it sets out to add to the knowledge over the factors associated with suicide ideation. It is hoped that the outcome of this study will serve a heuristic and seminal function for much broader socio-demographic

and epidemiological enquiry into the phenomenon aimed at uncovering the nuances regarding the factors and prevalence rate of suicidal ideation in Ghana among in-school adolescents.

METHODS

The study utilised secondary data from the 2012 Ghana Global School Health Survey (GSHS) organised by World Health Organisation (WHO) and Centres for Disease Control and Prevention (CDC). This was a school-based survey of students in grades SS1-3, which are mostly attended by students aged 13-17 years. The study used a two-stage cluster sample design in order to produce data representative of all students in grades SS1-3. In the first stage, schools were selected with probability proportional to enrolment size, while at the second stage, classes were randomly selected and all students in selected classes were eligible to participate. The school response rate was 100%, the student response rate was 82%, and the overall response rate was 82%. A total of 1648 students participated in the Ghana GSHS.

Data analysis was conducted using SPSS version 16. The variables that were used for analysis included sociodemographic characteristics, having considered suicide in the last 12 months, smoking, loneliness, parental understanding, involvement in a fight, whether someone was attacked or not, whether bullied or not, truancy, anxiety, alcohol abuse, alcohol intake, close friendship and food security. The frequencies were weighted. The determination of associations between the independent variables and dependent variable were done by using univariate and multivariate logistic regression analysis at 95% Confidence Interval (CI).

RESULTS

The total number of students that participated in the survey was 1,648, out of which 52.4% were males. Out of the total number of participants, 27.5% were aged less than 14 years, and 31.3% were 16 years or older. Table 1 presents selected characteristics of the study population. The analysis of these characteristics showed that 15.2% of the students did not have enough food. It was also found that 13.0% were anxious. Students who reported to have been lonely accounted for 13.2%. Students who reported truancy were 41.9%, and those bullied and attacked accounted for 62.1% and 48.5%, respectively. Among the students, it was also found that 10.0% and 48.4% smoked and were involved in a fight, respectively. The prevalence of suicidal ideation was 20.6% (21.7% among females and 19.2% among males).

Table 2 indicates variables that were associated with suicidal ideation. Age was associated with suicide ideation. Those students, who were less than 14 years old, were 12% less likely to contemplate on committing suicide than those aged 16 years or older. While those that were 15 years old were 7% less likely to think about committing suicide than those aged 16 years or older.

Male students were 7% less likely to entertain thoughts about suicide than females. Students with challenges with food security were 9% more likely to have suicide ideas compared to those without food challenges. Students with anxiety were 37% more likely to have thoughts about suicide compared to those without anxiety. Those students who were lonely were 39% more likely to contemplate on committing suicide. In addition to this,

students who were truant and had no close friends were 4% and 28%, respectively, more likely to have suicidal ideation.

*P = 0.068.

Bullied and attacked students were 10% and 6%, respectively, more likely to think about suicide than those who were not bullied or attacked, while those that smoked and involved in a fight were 34% and 11%, respectively, more likely to have thoughts about suicide than those that did not smoke and got involved in a fight. Students who abused alcohol and those that consumed alcohol in the previous 30 days to the survey were 16% and 11%, respectively, more likely to have suicidal thoughts than those who did not abuse alcohol and consume alcohol in the previous 30 days to the survey, and students without parental understanding

were found to be 9% more likely to have suicidal ideas than those with parental understanding.

DISCUSSION

This study found that the prevalence of suicidal ideation was 20.6%. Out of this, 21.7% females reported to have thought about committing suicide compared to 19.2% males who contemplated on suicide. The finding of this study is similar to what Omigbodun et al. [6] reported of 20% suicidal ideation prevalence among Nigerian students. In another study done in Zimbabwe [12], the prevalence was found to be 21.6% which is also similar to the finding of the present study.

According to a study done by Muula et al. [13] among Zambian students, suicidal ideation prevalence was established to be 32.2%, a finding that is higher than the finding of the present study. However, the prevalence of suicidal ideation among in-school adolescents in Ghana is still high at 20.6%, and there is need for proper measures to be put in place to reduce the vice.

In our study, students less than 14 years old and those aged 15 years were less likely to think about committing suicide than those aged 16 years old or older. This finding is similar to Liu et al. [14] and Rudatsikira et al. [15] findings who reported that the odds of suicidal ideation increased with increasing age. In another study done in Zambia by Muula et al. [13], they found that adolescents less than 14 years old were more likely to have considered committing suicide than those aged 16 years old or older, which is a direct opposite of our finding. The explanation could be that, the Zambian study enrolled more students who were less than 14 years of age. In addition to this, the period around 12-14 years in children is very critical, as this is when hormonal influence gets to be strong; therefore, more students are likely to be frustrated with little things which might drive them to wanting to take their own lives.

The finding that males were less likely to think about suicide than females differs with the results obtained by Muula et al. [13] who reported that males were more likely to consider committing suicide than female students. Nevertheless, Liu et al. [14] found a similar result to what the present study established, where it was found that females were more likely to seriously consider committing suicide than males. This is also supported by Ovuga et al. [16] who reported females to have had higher chances of committing suicide than males in two rural districts of Uganda. Despite having more females thinking about suicide in the present study and many others, it is the males who top in terms of deaths due to suicide [17]. This situation could be attributed to the differences in temperaments between males and females. Usually, females will just talk or think about suicide, but are not courageous enough to undertake the vice.

We also found that adolescents who had challenges with food were more likely to think about suicide than those without these challenges. This finding is congruent with a study done in Benin by Randall et al [18], who reported higher chances of those with food challenges to have had suicidal thoughts. It can therefore, be speculated that hunger can also lead to serious considerations of committing suicide due to its adverse health effects. However, many studies have not established the association of food security and suicidal ideation.

Our study found that students who reported anxiety were more likely to seriously consider committing suicide than those that did not report anxiety. This finding is similar to the finding by Omigbdun et al. [7] and Rudatsikira et al. [12] who found that anxiety was positively associated with suicidal ideation. However, the finding of the present study is contrary to the results of Dunlavy et al. [19] who reported that there was no association between anxiety and suicidal ideation among the school attending adolescents in Dar es Salaam, Tanzania. The reasons for this disparity are speculated to be due to the fact that, anxiety in the study by Dunlavy et al. [19] was not operationalised to capture the somatic experience and also, anxiety alone was not sufficient to warrant the association. In addition to this, the definition of anxiety in Dunlavy et al.'s study was different from the present study.

Loneliness was also found to be a risk factor in the present study. Students who reported loneliness were more likely to consider suicide than those who were not lonely. The finding is in tandem with Rudatsikira et al. [23] who found that loneliness was positively associated with suicide ideation. However, the finding from the present study contradicts the finding of Muula et al. [13] and Dunlavy [19], who reported loneliness to be negatively associated to suicide ideation. The difference in the findings may be as a result of the religious differences that exist among the countries. In some religions (i.e., Christianity), difficulties might strengthen them to fight on till a break through comes. In addition to this, they will even get examples from their religious figures who could have gone through difficulties and who could have led lonely lives. Therefore, students from such backgrounds will not entertain thoughts of suicide because it would be sinning against their supreme being.

Adolescents who had close friends were less likely to have thoughts about suicide. This result from the present study is similar to other studies done by Rudatsikira et al. [12] and Dunlavy et al. [19], who reported that adolescents who had no close friends were significantly more likely to have had suicidal thoughts. Nevertheless, Randall et al. [18] reported a higher chance of suicidal thoughts among those adolescents with close friends. This may be due to the violence acts that are very common in Benin where the study was conducted. The violent acts are normally done in gangs or groups who may all be friends.

Students who reported truancy in the present study were more likely to have suicidal thoughts than those who did not. This finding is not in agreement with the results obtained by Dunlavy et al. [19] who found that those students who reported truancy were less likely to consider committing suicide than those that did not report truancy. The disparity between the results could be explained by the differences in the prevalence rates of factors such as bullying, attacks, hunger, and alcohol abuses, which were lower in the study done by Dunlavy et al. [19] than the present study. The factors that have been listed above have been found to greatly influence truancy among adolescents according to Siziya et al. [20]. Therefore, it can be speculated that, in the event where truancy is not significantly associated with suicide ideation, those factors could be missing or having little influence in causing someone to have suicidal thoughts.

It was also observed in the present study that adolescents who were bullied were more likely to contemplate on suicide than those that were not bullied. The result is consistent with the results obtained from studies done by Rudatsikira et al. [21] and Omigbodun et al. [7] who reported higher chances of those bullied students thinking about suicide than those that were not. However, Dunlavy et al. [20] found no association between being bullied and having thoughts of suicide. This could be attributed to the lower prevalence rates of bullying

in that Tanzanian study done by Dunlavy et al. [20]. Another reason could be due to the differences in bullying rates by geography [21, 22].

Another finding from the present study was that being attacked was found to increase the chances of one thinking about suicide. This finding is similar to those found by Omigbodun et al. [7], Randall et al. [18] and Rudatsikira et al. [15] who established that being attacked was likely to increase the chances of one thinking about committing suicide. This finding might be due to the fact that, some attacks might leave the victims injured or raped as can be the case for the female students. This might make students to think about committing suicide to cover up the shame of rape, or avoid perpetual pain due to the injuries from the attacks.

Our study also found that students that smoked were more likely to consider committing suicide than those that did not report to have smoked in the previous 30 days. The finding is consistent with Rudatsikira et al. [15, 23], Muula et al. [13] and Omigbodun et al. [7] who reported an association between smoking and having thoughts about suicide. Generally, smoking makes people do things they can't do when they are normal, for young minds such as for these students, smoking may lead them to be involved in sexual activities. As a result, they may contract diseases such as HIV and STIs. These are some of the reasons that may cause students who may have been smoking to think about suicide. Others might even be involved in crime. Out of fear to be shamed or jailed, they might start thinking about committing suicide.

Adolescents in the present study that were involved in a fight were more likely to think about committing suicide than those that did not get involved in any fight. However, this finding differs from the finding by Randall et al. [18], who found that students, who were involved in a fight, were less likely to think about committing suicide than those that did not report getting into a fight. The difference may be attributed to the fact that, students that fight usually relieve their psychological pain, especially when they manage to beat the opponent. Therefore, the thoughts of being a hero override thoughts of wanting to end their lives. The opposite is true when they are involved in fights and lose.

In the present study, students with parental understanding were surprisingly found to be more likely to think about committing suicide than those without parental understanding. This is contrary to a study conducted in Guyana by Rudatsikira et al. [23] who reported students having parental understanding to be less likely to consider committing suicide compared to those that lacked the parental understanding. Other studies have also shown that parent-child conflict is one of the most common precipitating factors of suicide attempts [24]. In another study done by Heider et al. [25], they reported that among adults in the European Study of Epidemiology of Mental Disorders project, suicidality was associated with low parental care. Therefore, parental understanding is cardinal in reducing suicidal thoughts among adolescents in many other studies despite it not being an important positive factor in the present study.

Parents normally offer a listening ear that a child would not get from anyone in society; hence many would be comforted and abort all the thoughts of killing one-self. Despite all the good reasons of parental understanding, we have a certain type of parental understanding that can lead or encourage children/adolescents to entertain these suicidal thoughts. Such a type would be influenced by cultural or religious beliefs that may offer suicide as a solution whenever one is aggrieved. In addition to this, suicide is like a reward for whomever, dares to take such a path. These are some of the factors that could have been at play to produce such a result in the present study, where parental understanding was found not to be protective against suicidal thoughts like many studies have suggested or found.

Alcohol abuse was found to be significantly associated with suicidal ideation. Students that abused alcohol were more likely to think about committing suicide than those that didn't abuse alcohol. This finding is consistent with results obtained by Rudatsikira et al. [12, 15, 23] who reported that students that were in the habit of abusing alcohol were more likely to seriously consider suicide than those that didn't. An explanation to this could be that alcohol is a depressant, and many adolescents take alcohol in times of confusion as a result of social issues. After getting sober, reality dawns and are faced with more problems than ever, a recipe that is more likely to lead them to end their lives.

In conclusion, the prevalence of suicidal ideation in Ghana was high and could lead to high suicide rates. Therefore, with this understanding of the factors that are likely to influence the suicidal ideation among in-school adolescents in Ghana, strategies aimed at reducing adolescent suicide cases can focus on these factors.

ACKNOWLEDGMENTS

The authors extend their gratitude to the World Health Organization (WHO) and Centres for Disease Control and Prevention (CDC) for making the data from the Ghana Global Health Survey available for analysis. We also thank all the students who participated in the survey.

ABSTRACT

Suicidal ideation is considered to be an important precursor to later attempted and completed suicide. Suicide among children, even in developed nations, has been a neglected issue until recently. This situation has created a paucity of data on suicidal ideation, attempted suicide and suicide among adolescents in such populations. The objectives of the study were to estimate the prevalence of suicidal ideation as well as to determine factors associated with suicidal ideation among in-school adolescents in Gaza strip. We conducted secondary analysis of the Gaza strip Global School-Based Health Survey-2010 data. Assessments of associations were conducted through both weighted bivariate and multivariate logistic regression analyses at 95% confidence interval. The study recruited 2,607 students. Close to one fifth of both male (18.9%) and female (19.7%) students reported having seriously considered committing suicide. Having no close friends, current smoking, anxiety, victim of bullying, loneliness and experiencing challenges of food security were positively associated with suicidal ideation, while being male and having understanding parents were negatively associated with suicidal

ideations. Suicidal ideation is a major public health issue in Gaza strip. Measures aimed to prevent suicide should incorporate our understanding of the factors associated with suicidal ideation identified in this study together with pure Islamic values, principles, traditions and cultural issues that uphold parental support.

Keywords: suicidal ideation, prevalence, associated factors, adolescents, Gaza strip

INTRODUCTION

Suicidal behavior is a major contributor to morbidity and mortality worldwide [1]. World Health Organization (WHO) estimates that globally, approximately one million people kill themselves every year [2]. According to Anderson and Smith [3], suicide is the third leading cause of death among 15-to-24 year olds [4] and the work by Schwartz 2016 show that suicide is actually the second leading cause of death among college students. Therefore, WHO ranks suicide as the major global public health problem that needs implementation of national suicide prevention strategies.

While most research and prevention of suicide is carried out in the more affluent countries and receiving increased attention in many developed countries, it remains largely ignored in developing countries [5]. Some researchers are for the view that suicide should be considered as an important area of research in developing countries, especially impoverished rural populations because it is highly associated with mental health problems [6]. This perceived association with mental illness tends to impede the implementation of successful preventive programs hence the need for more research in such populations. Challenges impeding on research into suicide attempts and completed suicide among people with severe mental disorders in low-middle-income countries are many. For instance, such research is mostly limited to patients attending psychiatric facilities where selection bias is likely to be high [1]. It is also important to note that suicide is a hidden cause of death in traditional societies because of the high levels of stigma and associated religious and cultural condemnation [7].

Recent epidemiological evidence suggests that suicide is soaring among young people in the Middle Eastern countries, including Gaza strip. A number of factors have been associated with suicidal ideation in Gaza strip and studies [8] indicate that children and adolescents in Gaza Strip have been under continuous violence since the beginning of the second Intifada (Uprising). Other studies also indicate that alcohol drinking has negative effects on mental health and that this leads to a condition that causes psychiatric disorders and increases the risk of suicide [9], but we are not sure if this is relevant for this population in the Gaza strip. Therefore, the objectives of the study were to estimate the prevalence of suicidal ideation as well as to determine factors associated with suicidal ideation in order to suggest a framework for prevention of suicide among school going adolescents in the Gaza strip.

METHODS

Secondary data analysis was conducted using data obtained in the 2010 Gaza Strip Global School based Health Survey (GSHS) survey. The GSHS was developed by the WHO and the aim was to provide research data on health and social behaviors among school-going adolescents.

¹ unweighted frequencies. ² weighted percents.

The survey used a two-stage probability sampling technique, in which for the first stage, primary sampling units were schools which were selected with a probability proportional to their enrolment size. In the second step a systematic procedure was conducted among adolescents clearly indicating that they would not like to participate or by submitting a non-completed questionnaire. The overall response rate in the Gaza 2010 GSHS was 95% (School response rate of 100% and student response rate of 95%).

Variables that were used for analysis included having considered suicide, smoking, loneliness, parental understanding, in a fight, truancy, anxiety, close friendship, food security and key socio-demographic characteristics. Assessments of associations were conducted using both weighted bivariate and multivariate logistic regression analysis at 95% confidence interval.

RESULTS

The study recruited 2,607 school adolescents of which 51.0% were males. Results in Table 1 presents distributions of factors considered in the analysis by gender among the participants in Gaza strip, 2010. Selected characteristics of the study population showed that 88.3% of students had food security problems (most of the time or always went hungry because there was not enough food in the home). Female students reported anxiety and loneliness more than their male counterparts (20.4% and 16.5% among females compared with 12.4% and 13.7% among males, respectively). Few students (8.8%) reported having no close friends but truancy was common both among females (37.5%) and males (40.8%). A large proportion of students reported having been bullied (63.4% of males and 55.0% of female).

Slightly more than half (54.0%) of males and 38.6% of females reported having been attacked, and 49.8% of males and 31.4% of females reported being involved in a fight. Smoking was mainly reported among male students (19.0%) while parental understanding was reported in about one third (33.7%) of both male and female students. About 1 in 5 of both male (18.9%) and female (19.7%) students reported having seriously considered committing suicide.

Table 2 shows factors associated with suicidal ideation among junior high school students in the Gaza strip. Male students were 16% less likely (AOR = 0.84, 95% CI [0.82, 0.86]) to have suicidal ideation compared to female students. Students with food insecurity were 1.13 times more likely (AOR = 1.13, 95% CI [1.09, 1.17]) to consider committing suicide compared to students with food security. Anxious students were 58% more likely (AOR = 1.58, 95% CI [1.54, 1.63]) to have suicidal ideation compared to students who did not experience anxiety. Students who reported not to have close friends were 66% more likely (AOR = 1.66, 95% CI [1.60, 1.72]) to experience suicidal ideation compared to students who had close friends, while lonely students were 1.23 times more likely (AOR = 1.23, 95% CI [1.19, 1.26]) to consider committing suicide compared to students who did not report loneliness. Students with a history of involvement in a fight were 1.19 times more likely (AOR = 1.19, 95% CI [1.16, 1.22]) to consider committing suicide compared to students who never reported having been involved in a fight. Bullied students were 1.31 times more likely (AOR = 1.31, 95% CI [1.28, 1.35]) to have suicidal thoughts compared to students who were

not victims of bullying. Students who reported currently smoking were 65% more likely (AOR = 1.65, 95% CI [1.59, 1.70]) to have suicidal ideation compared to currently nonsmoking students. Students with parental understanding were 14% less likely (AOR = 0.86, 95% CI [0.84, 0.88]) to have suicidal ideation compared to students who did not have parental understanding.

DISCUSSION

The current study found a prevalence of suicidal ideation of 19.3% among in-school Gaza strip adolescents. This prevalence is lower than the rate found by Ghrayeb and colleagues [6]

among the Palestinian adolescents of 24.6%. However, our study finding is comparable to the reported rates in the neighboring countries of the Eastern Mediterranean Region and results of the previous international research work [10].

Results of the present study show that male students were 16% less likely to seriously consider committing suicide than female students. This finding is contrarily to the findings of the study among the Palestinian adolescents [6] and other previous reports [10, 11] that globally, the prevalence of suicidal behavior is consistently greater in males as compared to females. This is also supported by most previous studies [12, 13] that indicate that prevalence of suicidal ideation is higher among females than males. Age was found to be significantly associated with suicidal ideation and adolescents aged 14 years and below were less likely to have suicidal thoughts compared to the older participants. The result agrees with a finding in another study [14] and the explanation to this lays in part to higher prevalence of substance abuse and greater suicidal ideation in older adolescents.

Adolescents who reported to have food security challenges were found to be more likely to have suicidal ideas and this finding corresponds to the finding obtained elsewhere [15]. None availability of food in homes may have serious mental health problems for the young people that may result in a feeling that it is not worthy to live.

In the present study, anxiety was significantly associated with suicidal ideation. Similar finding has been reported elsewhere [16, 17] in which it has been reported that a preexisting anxiety disorder is an independent risk factor for subsequent onset of suicidal ideation.

Loneliness was associated with suicidal ideation in the current study and this is in conformity with other research work that found that living alone increased the risk for suicidal ideation among college students [18], suggesting that engagement in various activities with friends and having a well-established support system of friends can help in reducing suicidal ideas among in-school adolescents [19].

In addition, school adolescents in Gaza strip who reported truancy were more likely to have suicidal ideas compared to adolescents who did not have the habit of truancy. Other researchers also agree with our findings and in a European study [20], the analysis showed that there is a correlation between skipped school and suicidal behavior. Skipping school may be as a result of running away from being bullied. Alternatively, seriously thinking about committing suicide may result in skipping school. Because a cross sectional design was used in the current study, we are unable to ascribe causation in the relationship between truancy and suicidal ideation. Adolescents who had an experience in bullying were more likely to think of committing suicide compared to the others who did not experience bullying. Another study found a similar result and the finding was that adolescents who were being bullied and those who were bullies were at an increased risk of suicidal ideation [21].

Involvement in a fight has been associated with suicidal ideation in the present study. A study in the USA found that suicidal behavior might be associated with involvement in less extreme forms of violent behaviors, such as physical fighting [22]. In a similar finding, having been attacked was significantly associated with suicidal ideation in the present study, and another study in Peru [23] found that adolescents who had been attacked were more likely to have suicidal ideas compared to those that did not experience an attack. There is strong evidence that violence among adolescents is associated with suicidal ideation and efforts should be made to curtail this vice.

Smoking was significantly associated with suicidal ideation and this is in accord with the finding in another study elsewhere [24] where being a non-regular smoker was significantly

associated with lower odds of suicidal ideation. People may smoke to relieve stress that may in turn result in suicidal thoughts. Hence, further studies to directly link smoking to suicidal ideation are suggested.

Lack of parental understanding was significantly associated suicidal ideation and this is in accord with the observation in another study [25] in which the relationship of parental bonding to suicide ideation was examined. The study findings indicate that low parental care and high over-protection that indicate lack of parental understanding are associated with adolescent suicidality in general. Parental understanding would equally reduce levels of anxiety in the young population because in our findings, students who reported anxiety were 58% more likely to experience suicidal ideation which has also been noted as a risk factor for suicide in another study [24]. Improving the social, economic and political situation in the Gaza strip would help in reducing the levels of loneliness, increasing chances of students having close friends and encouraging positive parental-adolescent relationship.

In conclusion, most of the factors associated with suicidal ideation among in-school adolescents in Gaza strip are consistent with the prevailing situation in the Gaza strip. There is need to recognize suicidal ideation as an important issue among school adolescents in the Gaza strip. The design, implementation and evaluation of public health interventions aimed at reducing suicide rate in Gaza strip should incorporate our understanding of the factors associated with suicidal ideation that have been identified in the current study. Interventions should address the issue of violence against adolescents, fighting with peers, health risk behaviors especially initiation of smoking, and uphold supportive role of parents.

ABSTRACT

Worldwide, suicide is increasingly becoming an important public health problem. However, adolescent suicidal behaviour is a neglected public health issue especially in middle and low-income countries like Oman. The purpose of this study was to establish the prevalence and factors associated with suicidal ideation among adolescents in Oman. Analyses were based on secondary data from the 2010 Global School-Based student Health Survey (GSHS) conducted in Oman. Logistic regression analyses were performed to establish associations between the factors (i.e., food security, current alcohol use, bullying victimization, loneliness, anxiety, having no close friends, missed school, parental understanding, smoking, physical fights, physical attacks) and suicidal ideation. Suicidal ideation prevalence among adolescents (N = 1648) attending school was 10.2%. Out of this, more males (58.4%) contemplated on committing suicide than females (41.6%). There were no significant associations between exposure factors and suicidal ideation, except for cigarette smoking. Students who smoked were 2.43 (95% CI [1.38, 4.26]) times more likely to have considered committing suicide than those who did not

* Corresponding Author's Email: chitembusha@yahoo.com.

smoke. Although suicidal ideation in Oman was relatively low, smoking should be considered in the designing of interventions to further reduce suicidal ideation rate and subsequently suicide rate.

Keywords: suicidal ideation, prevalence, smoking, Oman

INTRODUCTION

An estimated 20% of the world's adolescents have a mental health or behavioural problem [1]. This has resulted in many of the children considering suicide. Suicidal behaviour is an important public health problem worldwide. According to World Health Organisation (WHO), more than 800,000 people died of suicide in 2000 [2]. In another report by WHO, more than one million people die annually as a result of suicide [3]. Suicide ranks as the fourth leading cause of mortality among adolescents aged 15-19 years [4]. In the age group 10-24 years, suicide is ranked the second leading cause of death [4]. These statistics show that suicide is a growing global public health problem among adolescents. In addition to this, suicidal ideation among adolescents is on the rise [5].

Dunlavy et al. [6] reported a prevalence of suicidal ideation of 7%. In a study conducted in the United States of America by Eaton et al. [7] among 14-18 years of age, a prevalence of suicidal ideation of 15% was reported. Rudatsikira et al. [8] found a prevalence of suicidal ideation of 18.4% among adolescents in Guyana. According to Randall et al. [9] and Muula et al. [10], 23.2% and 31.3% of the adolescents enrolled in their studies reported suicidal ideation, respectively. Despite these statistics, and the grave consequences of suicidal ideation among the adolescents and youth, suicidal ideation has remained a neglected public health issue across the entire globe; this includes developing and developed countries.

Oman is a 1000 mile long, coastal plain at the southeast tip of the Arabian Peninsula lying on the Sea and gulf of Oman. It is bordered by the United Arab Emirates, Saudi Arabia, and Yemen. There is paucity of data regarding suicidal ideation among adolescent in Oman. However, in a study conducted by Khalid et al. [11], 16.15% of the adolescents reported to have considered committing suicide in the United Arab Emirates, a country sharing a boarder with Oman. Nevertheless, there are no studies that have been done in Oman regarding suicidal ideation, though certain factors related to suicidal ideation have been studied such as bullying [12]. In that study, Al-Saadoon et al. [12] indicated that studies on bullying in Arab/Muslim countries are scarce, so are studies on suicidal ideation.

Suicidal ideation among adolescents is associated with several factors that include alcohol abuse [13-15], low parental understanding [16], bullying [17, 18], loneliness [19] and low social support [20]. There have been various reports on suicidal ideation and its correlates in developed countries [21, 22] but developing countries like Oman has limited data concerning the vice. We, therefore, carried out this study to estimate the prevalence and establish the correlates for suicidal ideation among adolescents in Oman.

METHODS

The present study used secondary data obtained from the Oman Global School-based Health survey (GSHS) organised by the World Health Organisation (WHO) and Centres for Disease Control and Prevention (CDC). Participants were students in grades 8 to 10. In order to produce data representative of all students in grades 8 to 10 in Oman, a two-stage cluster sample design was employed. During the first stage, schools were selected with probability proportional to enrolment size, while in the second stage, classes were randomly selected and all students in selected classes were eligible to participate in the survey. The response rate for the schools was 94%, while that of the students was 94%, and the overall response rate was 89%.

SPSS version 16 was used to conduct the analyses. Variables that were used in the analysis included socio-demographic characteristics, having considered suicide, smoking, loneliness, parental understanding, involvement in a fight, truancy, anxiety, close friendship and food security. Frequencies were weighted. Determination of associations between exposure variables and outcome variable was done using univariate and multivariate logistic regression analyses at 95% Confidence Interval (CI).

RESULTS

The Oman Junior High School survey (GSHS) enrolled a total of 1606 students, out of which 58% were males. The majority (36.4%) of students were aged less than 14 years. The rest were 15 and 16 years or older.

Table 1 presents characteristics of the participants in the study population. The results indicated that 11.9% of students had less food and 29% of them reported truancy. Analysis also showed that 31.1% of the students were bullied and 36.6% were attacked. Students who were involved in fighting accounted for 29.8% and those who smoked were 12.4%. It was also noted that among the participants, 25.4% abused alcohol, 24.0% lacked parental understanding and 10.2% were reported to have thought of committing suicide.

Table 2 shows factors that were associated with suicidal ideation. There were no significant associations between factors considered in the study and suicidal ideation, except for cigarette smoking. Students who smoked were 2.43 (95% CI [1.38, 4.26]) times more likely to have considered committing suicide than those who did not smoke.

DISCUSSION

The findings from this study indicate a prevalence of suicidal ideation of 10.2%. Out of this, 6.9% of the males reported suicidal ideation compared to 15.3% females who thought about committing suicide. This result is close to the finding by Dunlavy et al. [6] who reported 7% suicidal ideation among adolescents in Tanzania. However, it is significantly lower than rates found among school-going children of 20% in Nigeria [23], 14.5% in the United States [7], 31.3% in Zambia [10], 18.4% in Guyana [8] and 21.6% in Uganda [19].

The prevalence rate in the present study is also congruent with what was reported among Americans of Caribbean decent [24] of 10.7%.

¹ unweighted frequencies. ² weighted percents.

The lower suicidal ideation rates in Oman could be explained by the good economy that the country has. This good economy for the country enables easy access to various needs of humanity, ranging from shelter to food, and thus prevents change in behaviour that can lead to suicide. In a study conducted by O'Donnell et al. [25], it was established that those with unmet needs were at greater risk of thinking about committing suicide than those that had their needs met. This clearly shows a possible explanation for the low suicidal ideation rates in Oman. The needs of a larger population in Oman have been taken care of; therefore, the suicidal ideation is quite low. Though the suicidal ideation is quite low, there is need for the Oman government to put in place measures that will further reduce the prevalence rate of suicidal ideation.

The results from the present study show no significant associations between suicidal ideation and all the factors (age, gender, food security, truancy, bullying, being attacked, having been involved in a fight, alcohol abuse and parental understanding) except for cigarette smoking. Students who smoked cigarettes were 2.43 times more likely to have considered committing suicide compared to students who were not smokers. This finding is in tandem with various studies [15, 26]. Smoking as a drug may have ill-effect on the brain that may in turn lead to suicidal thoughts of the affected persons.

The factors that were not significantly associated with suicidal ideation in the present study have been reported to be positively associated with this vice in many studies [8-10, 18]. The non-significance of the associations between the exposure variables and outcome variable could be due to the similarities between students who had seriously thought about committing suicide and those who had not thought so in the present study. Having similar background characteristics between the two groups of students could result into non-significant associations. The other explanation would be the effect of confounders. If other factors that influence the outcome are unevenly distributed between the groups, these other factors can distort the apparent association between the outcome and the primary exposure of

interest; this might be the reason why the findings in this study show no association between the independent variables and outcome variable.

In conclusion, we found an overall relatively low prevalence of suicidal ideation among school going adolescents in Oman. Smoking should be considered in the designing of interventions to further reduce suicidal ideation rate and subsequently suicide rate.

ACKNOWLEDGMENTS

The authors give thanks to World Health Organization (WHO) and centres for disease Control and Prevention (CDC) for providing the data from the Oman Global Health Survey for analysis. To all students who participated in the survey, we say thank you, for without these participants, the study was not going to be a success.

ABSTRACT

Research on suicidal ideation and its correlates has not been given the right attention in Philippines; this is despite suicidal ideation being an important public health issue among adolescents. The aim of the present study was to determine the prevalence and correlates of suicidal ideation among adolescents in Philippines. The study used secondary data that was collected in a Global School-based Student Health Survey in 2010. Both bivariate and multivariate logistic regression analyses were performed to establish associations between the factors (i.e., food security, current alcohol use, bullying, loneliness, anxiety, having no close friends, missed school, parental understanding, smoking, physical fights and physical attacks) and suicidal ideation. Altogether, 5290 students participated in the survey. Overall, the prevalence of suicidal ideation was 17.0% (12.0% among males and 21.8% among females). Being of age <15 years, male gender and parental understanding were protective against suicidal ideation. The rest of the correlates were found to be risk factors of suicidal ideation. Among the risk factors that were established were; food security, anxiety, loneliness, having close

* Corresponding Author's Email: chitembusha@yahoo.com.

friends, truancy, bullying, physical attacks and fights, smoking and alcohol abuse. Suicidal ideation in Philippines was significantly high. Knowledge of the associated factors from the current study will enable implementation of interventions to reduce the suicide burden.

Keywords: suicidal ideation, suicidal behaviours, correlates, adolescent, Philippines

INTRODUCTION

Suicide is the fourth leading cause of death globally among the youth with age ranging from 15 to 19 years [1]. In addition to this, 6% of global deaths among youth aged 10-24 years are attributed to suicide [2]. Therefore, this makes suicide a major public health problem. Suicide has enormous social and economic costs to individuals and communities [3]. WHO [4] reported that suicide is a primary cause of death in the youth population worldwide. In Philippines, suicide is on the rise. Radaniel et al. [5] reported that there was an increase in the incidence of suicide cases in Philippines between 1984 and 2005, from 0.23 to 3.59% with the more females committing the act than males. These statistics indicate the need to formulate preventive measures that would curb the rising prevalence of suicide especially among the youth in Philippines.

According to Peter et al. [6], research on youth with suicidal thoughts is critical as suicidal ideation is a precursor to suicide completion. Studies among youth are cardinal due to the fact that many cases are occurring in this sub-population, especially among adolescents [7]. In a study by Page et al. [8] conducted in one of the towns in Philippines, suicidal ideation in adolescents was reported at 17.1%. Besides this study, other studies on suicidal ideation in both low and middle income countries have reported varying prevalence rates; 16% in Lebanon [9], 17.8%, in China [10] and 24% in Philippines. In African countries, the prevalence of suicide ideation is generally higher; 19.6% in Uganda, 23.1% in Botswana, 27.9% in Kenya and 31.9% in Zambia [8].

Philippines is an archipelago nation comprising 7107 islands that are mainly divided into three groups (Luzon, Visayas, and Mindanao) located in South East Asia [11]. In 2008, 21% of the estimated 90 million people living in Philippines were adolescents. Young people (aged 10-24 years) accounted for 30.5% of the population. The country has an active economy, with good rates of employment among youth that are aged between 15 and 19 years [12]. Although this is the case, many working youth are considered poor because they normally work for less than 1.25 dollars a day, a factor that is likely to affect adolescents and lead them to contemplate on committing suicide as a way of running away from economic hardships. Due to limited information on the suicidal ideation and its risk factors, the present study aimed to explore this area in order to provide knowledge that will be useful for interventions against suicide and suicidal ideation in Philippines.

METHODS

Our study utilised secondary data obtained from the Philippine Global School-based Health Survey (GSHS) carried out in 2011. This survey involved students in grades 1st to 4th. In order to rule out selection bias, the survey used a two-stage probability cluster sampling technique. Besides ruling out selection bias, the technique was used in order to produce data representative of all students in grades 1st to 4th. In the first stage sampling, the primary level involved the selection of schools which were chosen with probability proportional to the enrolment size. In the second stage, classes were randomly selected from the selected schools, and all students in selected classes were eligible to participate. A self-completed questionnaire was used to capture the information. The rate of response from the schools was 97%, while that of students was 82%; giving an overall response rate of 80%.

The outcome variable was self-reported suicidal ideation. The participants were asked to provide answers to questions about: their thoughts on suicide, age, gender, food security, their experiences on smoking and abuse of alcohol, their relationship with parents, whether they had close friends or not, having been bullied and attacked and truancy.

In order to reflect the likelihood of sampling each student, a weighting factor was utilised. In addition to this, the weighting reduced bias by compensating for differing patterns of non-response. SPSS version 16 was used to conduct logistic regression analyses in order to estimate associations between predictor variables and suicidal ideation at 95% Confidence Interval (CI). We reported unadjusted and adjusted odds ratios for selected predictor variables while considering suicidal ideation as the dependent variable.

RESULTS

A total of 5,290 adolescents participated in the Philipino Global school-based Health Survey (GSHS) in 2011. Out of the total number of participants, 50.2% were females. Most (26.9%) of the students were aged 16 years or older. Those aged less than 14 years accounted for 26.2%.

Table 1 gives the sample characteristics of the study population. Among the respondents, 6.8% reported not to have had enough food, 11.4% were anxious, 14.8% were lonely, 3.6% had no close friends and 33.9% reported missing school without permission. Furthermore, 47.6% were bullied, 33.2% were attacked, and 36.6% were involved in a physical fight. Other students reported smoking (13.9%) and abusing alcohol (20.6%). The prevalence of suicidal ideation was 17.0% (12.0% among males and 21.8% among females).

Table 2 presents variables that were associated with suicidal ideation. In terms of age, students less than 14 years old were 27% less likely to think about committing suicide than those aged 16 years or older. On the other hand, those students aged 15 years old were 21% more likely to contemplate on suicide than those aged 16 years or older. The table also shows males being 41% less likely to think about committing suicide than females. Students with anxiety were 18% more likely to entertain thoughts of committing suicide than those without it. Students who reported loneliness were 55% more likely to have thoughts about committing suicide than those who were not lonely. Furthermore, students who were truant and those who

had no close friends were 8% more likely to have suicidal thoughts compared to students who were not truant and those who had close friends, respectively.

Students that were bullied and attacked were 26% and 3%, respectively, more likely to think about suicide than those that were not bullied and attacked. Those that were involved in a fight and smoked were 15% and 32%, respectively, more likely to ponder over committing suicide than those who were not. In addition to this, students who consumed alcohol were 31% more likely to consider committing suicide than those who did not, while those that had parental understanding were 17% less likely to cogitate on committing suicide than those that did not have.

DISCUSSION

Our study found that overall 17% (12% males and 21.8% females) had seriously cogitated on committing suicide. This finding is much higher than the rate of suicidal ideation among the adolescents in Thailand (8.8%) [13], Myanmar (0.7%), Indonesia (4.0%) [14] and in Sri Lanka 9.9% [14]. The difference in the rates can be attributed to religion. In countries like Thailand, most people are Buddhists. In Buddhism, one has to train oneself against destroying life, as this would be practicing one of the immoral actions in the religion. Therefore, this religion practiced by Thai people or adolescents may play a role in preventing them from thinking about suicide as opposed to Filipinos who are mostly Christians. However, Christianity also speaks against suicide but might not be as strict as Buddhism.

Similarities in the prevalence rates of suicidal ideation between Philippines and other countries where Christianity is also practiced exist; 17.1% in Brazil [15] and 18.4% in Guyana [16]. Previous studies have reported similar findings with regard to more female adolescents considering suicide than males [17-19].

Results from the present study indicate that students less than 14 years together with those aged 14 year were less likely to contemplate on committing suicide than those aged 16 years or older. This result is similar to that found by Liu et al. [20] and Rudatsikira et al. [21] who established that increase in age was correlated with suicidal ideation. Contrary, Muula et al. [22] reported that adolescents aged less than 14 years were more likely to consider committing suicide than those aged 16 years or older. The explanation for the difference is not entirely clear. It might be speculated that in Muula et al.'s [22] findings, younger minds were more likely to succumb to life's pressures, hence the wish to take one's life. It might as well be that younger adolescents may not be as stressed as the older ones to result in having suicidal thoughts because the 'adolescence crisis' might not have taken its toll on the younger adolescents.

We also observed that adolescents who had no food were more likely to ponder on committing suicide than those that had enough to eat. This finding is in line with a study done by Randall et al. [23], who concluded that adolescent students who were hungry were likely to think about suicide compared to those that had enough food. The effect of lack of food causes various effects in young people, such as missing school which later leads to failure or school stoppage. Siziya et al. [24] also reported an association between lack of food and being truant or missing school without permission. This could explain why such adolescents with challenges of food could possibly and constantly think about killing themselves.

The present study also established that students who reported to have been anxious were more likely to contemplate on committing suicide compared to those that were not. This ties in very well with the finding by Omigbun et al. [25] who reported a positive association between anxiety and suicidal ideation. However, the finding in the current study differs with that obtained by Dunlavy et al. [26] in Tanzania. In that study, students who were anxious were less likely to think about suicide. We are unable to offer an explanation for this difference.

Lonely students were also found to be more likely to think about suicide compared to those who were not lonely. This is congruent with the finding of Rudatsikira et al. [21] who established a positive association between loneliness and suicidal ideation. However, Muula et al. [22] finding is not in tandem with the result from the present study. The difference may

be as a result of the social and cultural training that adolescents are exposed to in the setting where Muula et al. conducted the study. Otherwise, Stravynski and Boyer [27] also reported a positive association between loneliness and suicide ideation.

In the present study, lack of close friends was positively associated with suicide ideation. This is also reported by various studies [21, 22, 25]. However, Randall et al. [23] finding contradicts the results from the current study. The reason might not be very clear as to why having close friends might lead one to consider committing suicide, but, it can be explained by considering various frustrations that can be brought by close friends. Sometimes peers might introduce unnecessary competition as regards to material possessions. When one does not have what others who are close have, they might start thinking that it's not worth to live in a world full of struggles.

Truancy is defined as missing school without permission. Students who were truant in the present study were more likely to ponder over committing suicide compared to students that were not. Truancy may be necessitated by various factors such as bullying, attacks and fights at school. These factors might prevent adolescents from attending school regularly [24]. In studies where these factors were low in prevalence rates, like in Dunluvy's [26] study of adolescents in Tanzania, truancy was negatively correlated with suicidal ideation. The present study has higher prevalence rates of bullying, attacks and physical fights.

Bullying or victimization tends to influence negative thoughts in adolescents. Many begin to feel unwanted and hence the thought of ending it all through committing suicide. In the present study, students that reported having been bullied before were more likely to have thoughts of committing suicide compared to those that never experienced the vice. These findings are in line with those of Omigbodun et al. [25] and Owusu et al. [28] who established a positive association between Bullying and suicidal ideation. Other studies have found no association between the two variables [26]. The disparity in the results can be due to the lower rates of bullying in the later study and the effects of recall bias by some participants when it comes to recalling whether they had experienced the vice in the previous months before the study was conducted.

Another finding from the present study is an attack on an adolescent increases the chance of thinking about committing suicide. This finding is similar to results established by Omigbodun et al. [25] and Randall et al. [23]. Attacks may bring negative thoughts about one's life, a feeling that is likely to culminate into suicide. In some countries where suicide is considered to be a tool for retribution, when one is attacked, they are forced to start thinking about suicide so as to avenge the attacks they could have gone through in the past. This is common in Islamic countries where suicide is commonly practiced as it is part of the beliefs.

According to the findings of the present study, students that smoked were more likely to seriously consider committing suicide than those that did no smoke. This finding agrees with what Rudatsikira et al. [21] and Muula et al. [22] reported. Smoking tends to affect the normal operation of the brain; adolescents who indulge in such vices are likely to have thoughts about suicide. However, smoking might be linked to various factors such as having close friends and parents who are involved in the habit of smoking [29]. Other studies have also associated psychiatric illnesses to smoking [30-32]. These illnesses eventually might lead to someone getting frustrated with life, after which thoughts about killing oneself will be inevitable.

Our study also found that adolescents who had parental understanding were less likely to think about suicide. The present study agrees with the findings of Cash and Bridge [33] who established that having parental understanding was protective against suicidal ideation. The presence of parents who understand in one's life just makes things better, amidst of troubles; adolescents having parents who understand quickly find solutions as parents offer solutions and good listening ears. However, it is not everyone who has understanding parents who enjoys this privilege of care. In certain instances some adolescents are driven to start thinking about suicide due to the uncaring attitudes from their parents.

A significant association between alcohol abuse and suicide ideation was observed in the current study. Students who consumed alcohol were more likely to consider suicide than those that did not consume alcohol. The result is similar to what Rudatsikira et al. [21] found. It has been observed among adolescents that alcohol consumption is looked at as a solution to many social problems that might be prevalent in their lives. However, the habit of abusing alcohol just increases these problems and leads the adolescents to start thinking about suicide so as to alleviate the sufferings brought as a result of alcohol consumption.

In conclusion, suicidal ideation among school going adolescents in Philippines was high and risk factors associated with suicidal behaviour were identified. This information from the present study can be taken into consideration when developing and implementing interventions to prevent suicide.

ACKNOWLEDGMENTS

We are grateful to the World Health Organization (WHO) and centres for disease Control and Prevention (CDC) for making the data available for analysis. We also thank the Ministries of Education and Health for the support rendered. To all students who participated in the survey, we say thank you, for without these participants, the study was not going to be possible.

ABSTRACT

Suicidal ideation and its correlates have not been addressed within the Bahamian society despite its enormous effects on adolescents not only in Bahamas, but also all over the world. Statistics have indicated a rise in suicide cases in Bahamas. However, there is paucity of information regarding suicidal ideation and its correlates in Bahamas. The objectives of the current study were to estimate the prevalence of suicidal ideation and determine its correlates among adolescents in Bahamas. Secondary analyses were conducted using data obtained from the Global School-based student Health Survey (GSHS) carried out in 2013 in Bahamas. A backward logistic regression analysis was conducted to determine independent factors associated with suicidal ideation (i.e., food security, current alcohol use, bullying, loneliness, anxiety, having no close friends, missed school, parental understanding, smoking cigarettes and marijuana, physical fights, physical attacks) and suicidal ideation. Suicidal ideation prevalence among adolescents (N=1357) was 18.2% (13.8% among males and 22.3% among females). Male gender was protective against suicidal ideation. Other variables were found to be risk factors for suicidal ideation and these were; age below 16 years, anxiety, loneliness, bullied, physical fights, smoking cigarettes and parental understanding. Suicidal ideation in

Bahamas was notably high. Hence, the needs for interventions addressing the risk factors that have been identified in this study in order to curtail the prevalence rate of suicidal ideation.

Keywords: suicidal ideation, prevalence, risk factors, adolescent, Bahamas

INTRODUCTION

Suicide is the 14th leading cause of death worldwide. It accounts for 1.4% of the global burden of disease and 1.5% of all mortality [1, 2]. It is also known to be 3rd cause of death in adolescents, mainly those aged 15 years [3]. When compared to mortality rate due to war and homicide combined, the annual mortality rate as a result of suicide is greater [4]. The situation about suicide is more alarming as indicated by reports given about people that harm themselves through suicide. It is known that 2,000 people every day harm themselves through suicide. Suicide and suicidal attempts in Bahamas has become a major public health concern [5], with steady increase in the cases.

In other countries such as the United States of America, suicide is the tenth leading cause of death. It is observed that there are more deaths due to suicides than car accidents in that country (USA) [6]. According to the first report on suicide by WHO, one person commits suicide every 40 seconds [7]. Suicide starts with a thought before it can be completed. In Bahamas, there has been studies done in order to ascertain the rate of suicide cases, however, studies on suicidal ideation and its correlates have not been undertaken to greater detail. This fact is supported by Kava et al. [5] who stated that mental health was insufficiently addressed within the Bahamian society.

The Bahamas is a stable, developing nation with an economy heavily dependent on tourism and offshore banking. Though this country has been shown to be developing, it is one of the wealthiest Caribbean countries. In terms of poverty, 8.7% of the households are living in poverty, and poverty levels are significantly higher in family islands than in New Providence (12.4%) and in Grand Bahama (9.4%) islands. According to Kava et al. [5], one of the leading causes of these thoughts about suicide is a feeling of shame. The theory suggests that the shame gap usually occurs when one struggles with high expectations versus reality. The result of this will be someone contemplating on suicide. It would mean that someone is not dealing with the problem but with shame of failing to meet the expectations.

The above effects of thoughts on suicide can lead to increased death rate if not addressed in Bahamas. Kava et al. [5] reported a 3.7% suicide rate from 2000 to 2013. Though suicide rate of 3.7% is low, the rate of suicide attempts was reported to be between 6% and 23%, spanning from 2000 to 2012. Though the government through Central Detection Unit (CDU) is doing everything possible to reduce the cases, there are still deficits in the information pertaining to risk factors and prevalence rates of suicidal ideation. These missing elements are critical to prevention programmes. Hence, the objectives of the study were to estimate the prevalence of suicidal ideation and determine its associated factors.

METHODS

The present study involved secondary analysis of data for the Bahamas Global School-based Health Survey (GSHS) carried out in 2013. This survey was organised by World Health Organisation (WHO) and Centres for Disease Control and Prevention (CDC). The aim of the GSHS was to avail data on the prevalence of health behaviours and protective factors that could be used in evaluating school health and youth health programmes among young people aged 13 to 17 years. In the Bahamas GSHS, most young people in this age group were students in grades 8, 9, and 10. The GSHS used a two-stage cluster sampling method in order to produce data representative of all students in grades 8, 9, and 10 in Bahamas survey.

The first stage included schools being selected with probability proportional to enrolment size, while the second stage involved the random selection of classes. All students in selected classes therefore, were eligible to participate in the survey. Participants in this survey were required to self-report their responses to each question on a computer scannable answer sheet. The process was guided by well-trained research assistants that encouraged the students to answer all the questions; however, they were not forced to answer questions they were not comfortable to respond to. In the process, not all eligible students participated in the survey. The student and school response rates were 87% and 90%, respectively, giving an overall response rate of 78%.

Students indicated their age and gender on the questionnaire. They were also questioned on whether they had; challenges with food, experienced anxiety, been lonely in the previous 12 months, any close friends and whether they had missed school without permission. Information on how many students were bullied and attacked was also collected. Furthermore, participants were asked to state whether they had been involved in physical fights and smoked cigarettes and marijuana. The survey also sought to establish whether adolescents had parents who understood their problems and worries. Questions on whether students ever consumed alcohol and had ever thought about committing suicide were posed to establish the prevalence rates and later on determine factors that are associated with suicidal ideation.

The outcome variable was suicidal ideation that was experienced by the student in the previous 12 months before the study was undertaken. The independent factors were; age, gender, food security, anxiety, loneliness, having close friends, truancy, victimisation or bullying, physical attacks and fights, cigarette and marijuana smoking, alcohol abuse and consumption, and having parental understanding.

A weighting factor that was used in this analysis took into account differing patterns of non-response. The weight was:

$$W=W1 * W2 * f1 * f2 * f3 * f4,$$

where W1= the inverse of the probability of selecting the school

W2= the inverse of the probability of selecting the classroom within the school

f1= a school-level non-response adjustment factor calculated by school size category (small, medium, large)

f2= a class-level non response adjustment factor calculated for each school

f3= a student-level non response adjustment factor calculated by class

f4= a post stratification adjustment factor calculated by grade.

Using SPSS version 16, we generated weighted frequencies as estimations of prevalence rates of factors. Bivariate and multivariate logistic regression analysis was conducted at 95% Confidence Interval (CI) to establish the associations between the independent variables and suicidal ideation within the previous 12 months to the survey.

RESULTS

Adolescents who participated in the Bahamian Global school-based Health Survey (GSHS) in 2013 were 1357. Out of the total number of the enrolled students, 53.1% were females. About half (50.8%) of students were less than 14 years of age. Those aged 16 years or older accounted for 3.6%.

Table 1 shows the sample characteristics of the study population. Of the enrolled students, 7.0% reported to have had challenges with having enough food to eat, 14.1% experienced anxiety, 11.1% were lonely, 9.0% had no close friends and 14.5% were truant. In addition to this, 23.2% were bullied, 29.6% were attacked, and 39.5% were involved in a physical fight. Some students reported smoking cigarettes (5.4%) and marijuana (10.1%). Students that abused alcohol were 20.6%, and those that had cogitated on committing suicide were 18.2% (13.8% of males and 22.3% of females).

Table 2 presents factors that were associated with suicidal ideation after logistic analysis. Students less than 14 years old were 2 times more likely to seriously consider committing suicide than those aged 16 years or older. Meanwhile, students aged 14 and 15 years were 55% and 35% more likely to think about committing suicide than those 16 years or older. The table further indicates males being 23% less likely to consider committing suicide than females. Those students with anxiety were 89% more likely to puzzle over committing suicide than those without. Students who were lonely were 48% more likely to have thoughts about committing suicide than those who were not.

Students that were bullied and were involved in physical fights were 57% and 17%, respectively, more likely to contemplate committing suicide than those that were not bullied and involved in fights. Those that smoked cigarettes and marijuana were 17% and 51% respectively, more likely to think about committing suicide than those who did not. Furthermore, students who consumed alcohol were 19% more likely to seriously consider committing suicide than those who did not. On the other hand, those that had parental understanding were surprisingly 42% more likely to ponder over committing suicide than those that did not have.

Table 1. Distribution of factors considered in the analysis by gender among junior high school students in Bahamas, 2013

Factor	Total n ¹ (%) ²	Males n ¹ (%) ²	Females n ¹ (%) ²

DISCUSSION

Statistics from the current study show an 18.2% prevalence rate of suicidal ideation among adolescents attending school in Bahamas. The majority (22.3%) of participants who considered committing suicide were females. On the other hand, 13.8% of the males

experienced suicidal thoughts. The findings of the present study are similar to those obtained by Liu et al. [8] who reported 19% suicidal ideation in China. The results are also in line with the results found among adolescents in Nigeria [9]. However, the estimates are significantly lower than the 39.7% suicidal ideation among Viennese students [10] and 21.6% of the vice reported by Rudatsikira et al. [11] among Ugandan adolescents. Differences in the rates could be due to differences in the age structure, a relatively older population would likely have a higher prevalence of suicidal ideation because suicidal ideation rates increase with age [12].

The finding from the present study that males were 23% less likely to consider suicide is in congruent with findings of Liu et al. [8], Ovuga et al. [13], Lam et al. [14], Borges et al. [15], and McKeown et al. [16]. However, Muula et al. [17] established that males were more likely to consider committing suicide than females. This finding contradicts various studies [8, 13]. Although gender disparity in suicidal ideation in many studies is that females are more seriously going to ponder over committing suicide than males, males on the other hand are more likely to commit suicide and in a more violent manner [18]. It can further be assumed that females just think about committing suicide but they actually don't go on to kill themselves. In addition to this, Brezo et al. [19] found that female gender was also associated with a 2-3 times much likelihood of suicide attempts among Canadian-French participants.

We also observed that adolescents who experienced anxiety were more likely to cogitate on committing suicide than those that did not. The findings are similar to what Omigbun [9] found among adolescents in Nigeria. However, there was a difference with results obtained in Dunlavy's study [20]. The explanation for this disparity is not very clear, however, the Dunlavy's study could have been affected by recall bias.

Results from the current study shows that students less than 14 years old were more likely to think about committing suicide than those that were 16 or older. This is in line with findings of Muula et al. [17]. However, Liu et al. [8] found that adolescents who were less than 14 years were less likely to consider committing suicide than those 16 years or older. The explanation for the difference might not be clear, however, it might be that younger minds are likely to give in to life's problems hence the wish to commit suicide.

Students who reported to be lonely were found to be more likely to have considered committing suicide than those who were not. This finding is similar to that obtained by Stravynski and Boyer [21]. The finding from the present study is also in line with that of Rudatsikira et al. [11] who as well established a positive association between loneliness and suicidal ideation. However, Muula et al. [17], found loneliness to be protective against suicidal ideation. This finding from Muula et al. [17] is surprising because loneliness is a subjective experience of isolation. Therefore, persistent loneliness can alter behaviour and lead to mental disorders [5]. In addition to this, loneliness interferes with the ability to control emotions and can overtime derange perception of others. In the case of adolescents, this distortion in perception is what might bring about suicidal thoughts.

In the current study, bullied students were more likely to seriously consider committing suicide than those that were not. This finding is similar to what Owusu et al. [22] reported. However, Dunlavy et al. [20] observed no significant association between bullying and suicidal ideation. Bullying has bad effects on the victim; one of which is alienation, hence; suicidal thoughts linger in minds of adolescents who may experience bullying in order to escape from this vice. Students who were involved in physical fights were more likely to think about committing suicide than those that were not. This finding is not in tandem with what Randall et al. [23] reported in a study conducted among students in Benin. The disparity

in the results can be due to recall bias by some adolescents when it comes to recalling whether they had experienced the vice in the previous months before the study was carried out.

Another finding from the current study was that adolescents who smoked cigarettes were more likely to seriously consider committing suicide than those who did not. This finding is in tandem with that of Rudatsikira et al. [11] who also establish a positive association between smoking cigarettes and suicidal ideation. Burge et al. [24] also found that alcohol or cannabis use was positively associated with suicidal ideation. The effects of smoking and alcohol consumption may range from mental confusion to mental illnesses. This situation is likely to lead to alienation from others. The shame as a result of these mental confusions may trigger thoughts of wanting to kill one self.

We also found that students who had a good relationship with their parents were more likely to think about suicidal ideation than those that did not. This finding contradicts the findings of several authors [11, 25] who found that having a good relationship with a parent protected adolescent students against suicidal ideation. The finding in the current study suggests that a sound relationship between parents and children may not always yield positive results. Adolescents may take advantage of this good understanding attribute of the parents and indulge in various activities such as unsafe sexual activities and end up being infected. Adolescents in such situations may likely think about committing suicide.

According to the findings of the present study, students that consumed alcohol were more likely to ponder over suicide than those that did not. This finding is congruent with the finding of another study [11]. Alcohol has several effects on the mental health of an individual. The mental stability is distorted if one indulges in alcohol consumption. These effects are even worse for young people. Due to the depressant effects of alcohol, adolescents who engage in beer drinking are left with no option but think of a way to remove the shame that comes as a result of activities associated with drunkenness. Such adolescents contemplate on committing suicide more than they would focus on constructive activities. Furthermore, the present study found that students that smoked marijuana were more likely to consider committing suicide than those who did not. The finding is in agreement with that obtained by Muula et al. [17] study who reported that marijuana use was associated with suicidal ideation. Marijuana also known as cannabis has been used by adolescents to self-medicate in times when they have experienced the thoughts of wanting to kill themselves [26].

The present study had several limitations. The data was collected from school-going adolescents and may not represent all the adolescents in Bahamas. The mode of reporting or responding to questions in the questionnaire was self-reporting and therefore, mis-reporting was possible whether on purpose or just to avoid giving right answers about themselves. Due to the cross sectional design of the study, causation could not be ascribed to the associations that were observed in the current study.

In conclusion, suicidal ideation among adolescents in Bahamas was notably high. The factors associated with suicidal ideation from the current study might be useful in the development and implementation of measures to reduce the prevalence of suicidal ideation.

ACKNOWLEDGMENTS

We are grateful to the World Health Organization (WHO) and Centres for Disease Control and Prevention (CDC) for providing the secondary data for analysis. Sincere gratitude also goes to the Ministry of Health for the support rendered. To all students who were enrolled in the survey, we are appreciative of their participation in the study.

ABSTRACT

Suicide is a global public health problem which may start with seriously thinking about how to commit it. Although a study was previously conducted on the prevalence and correlates for suicidal ideation in Jamaica, it was based on a limited sample size and possible factors for suicidal ideation. Weighted logistic regression analyses (bivariate and multivariate) were conducted to establish significant factors associated with suicidal ideation. Unadjusted odds ratio (OR) and adjusted odds ratio (AOR) together with their 95% confidence intervals (CI) are reported. Of the 1,623 students who participated in the survey. Overall, 24.8% (23.0% of male and 25.8% of female) students reported suicidal ideation. Factors associated with suicidal ideation were age, gender, food security, anxiety, loneliness (AOR = 2.01, 95% CI [1.97, 2.05]), close friends (AOR = 1.25; 95% CI [1.22, 1.28]), truancy, bullied (AOR = 1.11; 95% CI [1.10, 1.13]), currently smoked cigarettes (AOR = 1.19; 95% CI [1.17, 1.22]), alcohol consumption [currently drank

* Corresponding Author's Email: ssiziya@gmail.com.

alcohol (AOR = 1.21; 95% CI [1.19, 1.23]) and alcohol abuse (AOR = 1.22; 95% CI [1.20, 1.25]) and parental understanding (AOR = 0.95; 95% CI [0.93, 0.97]). The prevalence of suicidal ideation in Jamaica among adolescents is high. In designing interventions for adolescent mental health and suicide prevention, unhealthy lifestyles and social relationships should be considered.

Keywords: suicidal ideation, prevalence, associated factors, adolescents, Jamaica

INTRODUCTION

Suicide is a global public health problem with 6% of all deaths among young people aged 10-24 years worldwide being attributed to suicide [1]. The rate for suicide in Jamaica is estimated at 2.0–2.7/100,000 population [2]. Suicide is an act of taking one's own life in response to overwhelming, unbearable emotional pain [3] and it can be prevented. One way to prevent suicides is to avoid suicidal ideation that is defined as thoughts, ideas and the desire to commit suicide [4].

The World Health Organization (WHO) and Centers for Disease Prevention and Control (CDC) have conducted a survey, the Global School-Based Health Survey (GSHS), in over 80 countries worldwide to assess health of adolescents aged 13–17 years [5]. Data from this survey have been used to determine magnitudes of adolescent suicide ideation [6] and variety of factors associated with suicidal ideation [4, 7-11]. The prevalence rate of suicidal ideation varies between countries and continents but risk factors have not varied [12]. However, risk factors may differ across surveys due to differences in study populations and sets of risk factors that are considered in analyses.

Figure 1. Map of Jamaica with its neighbouring countries.

Although a study was conducted on suicidal ideation in Jamaica [13], this study only covered Western Jamaica and the significant factors associated with suicidal ideation were sexual abuse, mental health diagnoses other than depression, self-violence, and ease of access to lethal substances/weapons. A limited sample of 342 adolescents aged 10-19 years from 19 schools in Western Jamaica participated in the survey. The GSHS obtained data from a nationally representative sample and covered more variables different from the ones covered by Kukoyi et al. [13]. It is thus imperative that further studies on suicidal ideation be conducted in Jamaica. High rates of suicidal ideation of 19.8% among boys and 25.7% among girls (overall 23.0%) aged 13-15 years have been reported in Jamaica [14] but not the correlates for suicidal ideation in the same sample of students in the GSHS. Hence, the objective of the current study was to determine prevalence of suicidal ideation as well as factors associated with suicidal ideation among students in grades 7-12 in Jamaica.

METHODS

Further analysis of the 2010 Jamaica GSHS data [15] was conducted. The survey assessed among other factors, mental health of the students. Details of the survey have been described elsewhere [16]. However, in brief, the 2010 Jamaica GSHS was a cross sectional study administered to individual students in grades 7-12 by a self-administered questionnaire.

Students were selected using a two-stage cluster sampling technique. Schools were first selected with probability proportional to enrollment size. Classes were then randomly selected and all students in selected classes were eligible to participate. All the schools that were selected to participate in the survey agreed to do so. An overall response rate of 72% was achieved.

Although the surveys are run by CDC and WHO, the data sets belong to countries. However, two years after completing the survey, the data set and code book associated with the core GSHS questionnaire modules are made available to the public. Only data from core GSHS questions are made public and no school or student identifiers are available.

Data was analyzed using SPSS version 16. The dependent variable was suicidal ideation that was obtained by asking the question 'During the past 12 months, did you ever seriously consider attempting suicide?' Variables were recoded as shown in Table 1. Frequencies were weighted using the following weighting factor:

$$W = W1 \times W2 \times f1 \times f2 \times f3 \times f4$$

where W1 = the inverse of the probability of selecting the school, W2 = the inverse of the probability of selecting the classroom within the school, f1 = a school-level non-response adjustment factor calculated by school size category (small, medium, large), f2 = a class-level non-response adjustment factor calculated for each school, f3 = a student-level non-response adjustment factor calculated by class, and f4 = a post stratification adjustment factor calculated by grade.

Weighted logistic regression analyses (bivariate and multivariate) were used to establish significant factors associated with suicidal ideation. Unadjusted odds ratio (OR) and adjusted odds ratio (AOR) together with their 95% confidence intervals (CI) are reported.

Table 1. Global School-Based Health Survey questions used in the analysis of adolescent suicidal ideation

Variable	Question	Coded	Recoded
Dependent variable			
Suicidal ideation	During the past 12 months, did you ever seriously consider attempting suicide?	1 = Yes; 2 = No	1 = Yes; 2 = No
Independent variables			
Age	How old are you?	1 = 11 years old or younger; 2 = 12 years old; 3 = 13 years old; 4 = 14 years old; 5 = 15 years old; 6 = 16 years old or older	1-3 = 1; 4 = 2; 5 = 3; 6 = 4
Gender	What is your sex?	1 = Male; 2 = Female	1 = 1; 2 = 2
Food security	During the past 30 days, how often did you go hungry because there was not enough food in your home?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Anxiety	During the past 12 months, how often have you been so worried about something that you could not sleep at night?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Loneliness	During the past 12 months, how often have you felt lonely?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Close friends	How many close friends do you have?	1 = 0; 2 = 1; 3 = 2; 4 = 3 or more	1 = 1; 2-4 = 2
Truancy	During the past 30 days, on how many days did you miss classes or school without permission?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 or more days	1 = 2; 2-5 = 1
Bullied	Bullied during the past 30 days, on how many days were you bullied?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Attacked	During the past 12 months, how many times were you physically attacked?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1
In a fight	During the past 12 months, how many times were you in a physical fight?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1
Currently smoked cigarettes	During the past 30 days, on how many days did you smoke cigarettes?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Parental understanding	During the past 30 days, how often did your parents or guardians understand your problems and worries?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	1-3 = 2; 4-5 = 1
Alcohol abuse	During your life, how many times did you drink so much alcohol that you were really drunk?	1 = 0 times; 2 = 1 or 2 times; 3 = 3 to 9 times; 4 = 10 or more times	1 = 2; 2-4 = 1
Currently drank alcohol	During the past 30 days, on how many days did you have at least one drink containing alcohol?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1

Table 2. Distribution of factors considered in the analysis by gender among junior high school students in Jamaica, 2010

RESULTS

Of the 1,623 students who participated in the survey, 51.4% were males and 13.1% were aged less than 14 years. Overall, 13.5% of the students reported that they had no food security. About 1 in 5 students reported being anxious (19.0%) and lonely (19.5%). Most

(88.4%) of the students had close friends. About a third (39.2%) of the students missed school or classes without permission. Over 4 in 10 students were involved in violence: 41.8% were bullied, 45.8% were attacked and 50.2% were involved in a fight. Current cigarette smoking was reported by 32.0% of males and 16.8% of females. Meanwhile, alcohol abuse was reported by 46.7% of males and 30.0% of females; and current alcohol use by 60.8% of males and 50.3% of females. About 1 in 4 of the students reported that they had suicidal thoughts: 23.0% of males and 25.8% of females with an overall rate of 24.8%. These results are shown in Table 2.

Correlates for suicidal ideation are shown in Table 3. All the factors considered in the analysis were significantly associated with suicidal ideation in bivariate analyses. However, in Multivariate analysis, the variables 'attacked' and 'in a fight' were not significantly associated with suicidal ideation. Students aged less than 14 years (AOR = 1.19; 95% CI [1.14, 1.23]) and those of age 15 years (AOR = 1.10; 95% CI [1.07, 1.13]) were more likely to have suicidal thoughts than students aged 16 years or older. Male students were 14% (AOR = 0.86; 95% CI [0.84, 0.87]) less likely to have suicidal ideation compared to female students. Students from homes that had no food security were 44% (AOR = 1.44; 95% CI [1.41, 1.47]) more likely to have suicidal ideation.

Compared to students who were not anxious, students who were anxious were 8% more likely to have suicidal ideation (AOR = 1.08; 95% CI [1.06, 1.10]). Meanwhile, students who were lonely were 2.01 (95% CI [1.97, 2.05]) times more likely to have suicidal thoughts compared to students who were not lonely. Students who had no close friends were 25% (AOR = 1.25; 95% CI [1.22, 1.28]) more likely to have suicidal thought compared to students who had close friends. Missing school or classes was positively associated with suicidal ideation (AOR=1.07; 95% CI [1.05, 1.09]).

Students who were bullied were 11% (AOR = 1.11; 95% CI [1.10, 1.13]) more likely to have suicidal ideation compared to students who were not bullied. Compared to students who did not smoke cigarettes, students who smoked cigarettes were more likely to have suicidal ideation (AOR = 1.19; 95% CI [1.17, 1.22]). Alcohol consumption was positively associated with suicidal ideation: alcohol abuse (AOR = 1.22; 95% CI [1.20, 1.25]); and currently drank alcohol (AOR = 1.21; 95% CI [1.19, 1.23]). Students who had parental understanding were less likely to have suicidal ideation (AOR = 0.95; 95% CI [0.93, 0.97]).

DISCUSSION

About 1 in 4 of the students in the current study reported that they had suicidal thoughts: 23.0% of males and 25.8% of females with an overall rate of 24.8%. The following factors were associated with suicidal ideation in the current study: age, gender, food security, anxiety, loneliness, close friends, truancy, bullied, currently smoked cigarettes, alcohol and parental understanding. The observed rate of 23.0% in the current study is much higher than the 9.7% that was previously reported by Abel et al. [17] among the school-going children aged 10-15 years. The observed high rate of suicidal ideation in the current study can partly be explained by the economic hardship that the population had been facing in Jamaica. The Jamaican economy was in recession between 2004 and 2010 and worsened by hurricanes in 2004 and 2007. The heavy rains caused widespread damage to agriculture and mining [18]. The effects of the hurricanes and floods may have had untold mental health effects on the population, and life might not have been worth living for the affected persons; and adolescents are at the greatest risk for suicidal ideation [19].

The prevalence of suicidal ideation was higher in females than males. Similar findings have been reported before [20, 21]. The higher rate of suicidal ideation in females may be due to the higher rate of depression in this gender than male gender [22] as a result of more girls experiencing sexual abuse than boys [23]. However, in some studies [24, 25] no significant associated has been reported between gender and suicidal ideation. Yet in a study by Muula et

al. [26], males were more likely to have suicidal thoughts than females. Cultural differences in different populations relating to gender may partly explain differences observed in the relationship between gender and suicidal ideation.

The finding that students aged less than 14 years were more likely to have suicidal thoughts compared to those aged 16 years or older accords the finding by Muula et al. [26]. Adolescence is a period of identity crisis that may result in mental ill health. However, this finding is not universal as other researchers have not found a significant association between age and suicidal ideation [11, 27-29].

Anxiety has been reported to be significantly associated with suicidal thoughts [11] and so is it from the current study. Information is needed to understand what is making students anxious so that interventions can be implemented to curtail suicidal ideation. The finding from the current study that those who were lonely were about twice likely to have suicidal thoughts compared to those who were not lonely contradicts the finding by Muula et al. [26] who reported that those who were lonely were less likely to have suicidal thoughts. By the cross sectional design of both studies, it is possible that loneliness may lead to suicidal thoughts and conversely because of thinking about taking one's own life, the individual may be withdrawn from public. In either case, companionship is encouraged to avoid suicide. Truancy has been associated with suicidal ideas in the current study. This finding accords that of D'Aulerio et al. [30]. It is possible that skipping school that may be as a result of depression may lead to suicidal ideation. Alternatively thinking about taking one's own life may make one abscond from school. Further studies are needed to elucidate this relationship between truancy and suicidal ideation.

Bullying that can be physical or emotional has been reported in previous studies to be associated with suicidal ideation [8, 11, 28, 31]. A similar finding is reported in the current study. In bullying, bullied students are rejected and abused by their peers and could lead to suicidal thoughts [32]. Bullying can be stressful and it is important to stop bullying in schools [33]. It is thus important that violence is prevented among adolescents to avoid suicidal thoughts.

Substance abuse has been shown to be associated with suicidal ideation. The present study revealed a significant association between smoking and suicidal ideation. Similarly, previous studies have also observed smoking to be significantly associated with suicidal ideation [9, 27, 29, 34, 35]. Alcohol consumption has frequently been reported to be associated with suicidal ideation [8, 11, 26, 36]. Further, alcohol abuse was also associated with suicidal thoughts in the present study and in other previous studies [11, 34]. Rossow et al. [37] argued that substance abuse may augment depressive thoughts and trigger ideation, suggesting that substance use may not directly affect suicidal ideation. Because early initiation of smoking and alcohol consumption are associated with adolescent suicidal ideation [38, 39], prevention of smoking and alcohol consumption among adolescents may be useful in preventing suicide thoughts and in turn suicides. However, not all people with suicidal thoughts end up committing suicide [40].

Poor child-parent relationship may cause developmental issues [41, 42] such as poor physical and emotional status, as well as social and cognitive development that may lead to suicidal thoughts [43]. Lack of parental support was also reported to be associated with suicidal ideation [11]. In the present study, students without close friends were more likely to have suicidal thoughts compared to those with close friends. Social support is important in preventing suicidal thoughts and eventually suicide.

In conclusion, the prevalence of suicidal ideation in Jamaica among adolescents is high. In designing interventions for adolescent mental health and suicide prevention, the following should be considered: prevention of bullying among adolescents, encouraging healthy relationships with friends and parents, and discouraging initiation of smoking and alcohol consumption.

ABSTRACT

Suicidal ideation and its factors have not received attention in Pakistan despite it being a global public health problem among adolescents. Although suicidal ideation is still of major public health importance, some studies indicate a drop in suicide rates in the last decade. However, there are few studies that have been conducted in Pakistan to address this vice. The aim of the present study was to determine the prevalence and factors of suicidal ideation among in-school adolescents in Pakistan. Therefore, the findings from the current study will aid the formulation of prevention programmes aimed at reducing the prevalence of suicidal ideation. Secondary data from the 2009 Pakistan Global School-Based student Health Survey (GSHS) was analysed using bivariate and multivariate logistic regression analyses at 95% confidence interval. The prevalence of suicidal ideation among in-school adolescents (N = 5192) was 7.2% (7.6% of males and 6.7% of females). Being of age <15 years, male gender, being attacked and parental understanding were protective against suicidal ideation. The rest of the correlates were found to be risk factors (food security, anxiety, loneliness, having close friends, truancy,

* Corresponding Author's Email: chitembusha@yahoo.com.

bullying, fights and smoking cigarettes) of suicidal ideation. The results from the present study indicate the need to provide adequate intervention programmes that will effectively curb the prevalence rates of suicidal ideation in Pakistan.

Keywords: suicidal ideation, prevalence, risk factors, adolescent, Pakistan

INTRODUCTION

Worldwide, suicide accounts for an estimated 6% of all deaths among young people [1] and is the fourth leading cause of death globally among the youth with age ranging from 15-19 years [2]. Thus, suicide is a major public health problem. Low and middle-income countries are home to more than 90% of the world's children and youth and also account for over 75% of global suicide deaths [3]. According to a study by WHO [4], it was reported that suicide is a primary cause of death in the youth population around the World. In Pakistan, suicide ideation has been under studied.

According to a study by Nock et al. [5], suicidal ideation often emerges in adolescence and is more common among females. There is need for more research on youth with suicidal thoughts as it is a precursor to suicide completion [6]. Studies on suicidal ideation in both low and middle income countries have produced varying suicidal rates; lower rates of 16% in Lebanon [7] and 17.8% in China [8]; higher in prevalence in some African countries: 19.6% in Uganda, 23.1% in Botswana, 27.9% in Kenya, and 31.9% in Zambia [9]. In Pakistan, Masood [10] reported a prevalence of 3.3%.

Factors associated with risk of adolescent suicidality have been identified as; being female, exposure to bullying and violence, alcohol and drug use, mental disorders and weak family and peer relationships [11-13]. However, the risk factors that influence suicide can be summarised as; psychiatric, biological, social and environmental. In Pakistan, Shaikh [10] found that anxiety, having close friends, parents checking homework and smoking were significantly associated with suicidal ideation. However, the results of this study [10] cannot be compared with results from similar studies because of differences in statistical methods, categorization of factors and factors considered in the analyses. Nevertheless, factors associated with suicidal ideation may vary according to populations within and among different countries. Thus, it is important that studies are conducted to establish factors that may be useful in formulating interventions to curb suicidal ideation in specific populations.

METHODS

The present study utilised secondary analysis of existing data from the Pakistan Global School-based Health Survey (GSHS) conducted in 2009. This survey involved students in grades 8 to 10. The survey used a two-stage probability cluster sampling procedure in order to rule out bias. In addition to ruling out selection bias, the procedure aided the production of data representative of all students in Pakistan. The first stage of sampling involved the selection of schools chosen with probability proportional to the enrolment size. On the other hand, the second stage comprised selecting classes from the selected schools. A self-

completed questionnaire was implored to capture the information. The response rate from the schools was 88%, while that of students was 87%.

The dependent variable was suicidal ideation, while independent variables were: age, gender, food security, smoking cigarettes, parental understanding, close friends, having been bullied and attacked and truancy. A weighting factor was utilised in the current study with the aim of reflecting the likelihood of sampling each student. Furthermore, weighting the sample further reduced bias by compensating for differing patterns of non-response. As a result, data analyses were weighted. SPSS version 16 was used to conduct a backward logistic regression analysis so as to determine associations between independent variables and suicidal ideation at 95% confidence interval.

RESULTS

A total of 5,192 adolescents participated in the survey of which 61.2% were males. The majority (38.9%) of the students were aged 14 years. Those aged 16 years or older accounted for 3.1%. Table 1 shows the sample characteristics of the participants. Among the respondents, 5.8% reported to have had challenges in accessing food, 8.4% were anxious, 12.2% were lonely, 8.0% had no close friends, and 23.4% reported to have been truant. In addition, 41.3% were bullied, 34.1% were attacked and 37.4% were involved in physical fights. Other students reported to have smoked cigarettes (6.3%). The prevalence of suicidal ideation was 7.2% overall.

Table 2 presents variables that were significantly associated with suicidal ideation. Students less than 14 years old were 13% less likely to cogitate about committing suicide than those aged 16 years or older. Furthermore, students aged 15 years old were 5% more likely to contemplate on suicide than those aged 16 years or older.

In addition, Table 2 also shows males being 7% less likely to ponder over committing suicide than females. Students with anxiety were 72% more likely to have thoughts of committing suicide than those without. Students who reported loneliness were 21% more likely to consider committing suicide than those who did not. Furthermore, students who were truant and had no close friends were 19% and 43%, respectively, more likely to have suicidal thoughts. Students that were bullied were 19% more likely to think about committing suicide than those that were not bullied. Surprisingly, students that were attacked were 2% less likely to have considered committing suicide than those who were not attacked. Students that were involved in a fight and smoked were 12% and 41%, respectively, more likely to ponder over committing suicide than those who were not. Furthermore, students who had parental understanding were 11% less likely to cogitate on committing suicide than those that did not have understanding parents.

DISCUSSION

Our study found an overall suicidal ideation prevalence of 7.2% (7.6% among males and 6.7% among females). This finding is similar to the rate of suicidal ideation among the adolescents in Thailand (8.8%) [14] and Sri Lanka 9.9% [15]. However, the suicidal ideation

rate in the current study is higher than that reported by Shaikh [10], despite both studies using the same data set. It is possible that the difference could have been due to transcribing error.

Table 1. Distribution of factors considered in the analysis by gender among adolescents attending school in Pakistan, 2009

Factor	Total n ¹ (%) ²	Males n ¹ (%) ²	Females n ¹ (%) ²

Previous studies have reported findings with regard to more female adolescents considering suicide than males [16-18]. The finding in the current study confirms this finding. The results from the current study also show that students less than 14 years and those aged 14 years were less likely to consider committing suicide than those aged 16 years or older. This result is similar to that found by Liu et al. [19] who established that increase in age was

associated with suicidal ideation. However, Muula et al. [20] reported that adolescents aged less than 14 years were more likely to consider committing suicide than those aged 16 years or older. The explanation for this difference is not well known. It might be that younger adolescents may not be as stressed as the older ones to result in having suicidal thoughts because the ‘adolescence crisis’ might not have greatly affected younger adolescents. Alternatively, younger adolescents may not have developed coping strategies for stress arising from the ‘adolescent crisis,’ resulting in the younger adolescents being more likely to have suicidal thoughts than older adolescents as reported by Muula et al. [20].

Table 2. Factors associated with suicidal ideation among adolescents attending school in Pakistan, 2009

Factor	Unadjusted odds ratio (95% CI)	Adjusted odds ratio (95% CI)
Age (years)		
<14	0.78 (0.77-0.79)	0.87 (0.86-0.88)

It was also observed in the current study that adolescents who had challenges with food were more likely to think about committing suicide than those that had enough to eat. This finding is congruent with a study done by Randall et al. [21], who concluded that adolescent

students who did not have enough to eat were likely to ponder on committing suicide compared to those that had enough food. Biologically, food plays a role in thinking abilities. Adolescents that lack food may be prone to engaging themselves in a cluster of unhealthy behaviours such as alcohol abuse, stealing and sexual intercourse that would depress them and later lead to suicidal thoughts.

The current study also found that students who reported to have been anxious were more likely to ponder on committing suicide compared to those that were not. However, the finding in the current study differs with that obtained by Dunlavy et al. [22] in Tanzania. In that study, students who were anxious were less likely to consider committing suicide than those who were not. A clear explanation for this difference is difficult to find and calls for further studies in establishing the association between anxiety and suicidal ideation.

We further established that lonely students were more likely to think about committing suicide compared to those who were not. This is in line with the finding of Rudatsikira et al. [23] who found a positive association between loneliness and suicidal ideation. On the contrary, the finding by Muula et al. [20] is not congruent with the result from the current study. The disparity may be as a result of the social and cultural teachings that adolescents are exposed to in the setting where Muula et al. carried out the study.

Lack of close friends was found to be positively associated with suicidal ideation. This is also reported by Omigbodun [24]. However, the result by Randall et al. [21] contradicts the finding from the present study. The explanation for this difference is not clear. However, while positive social support from close friends might protect adolescents from suicidal ideation, peer pressure arising from close friend may in turn result in thoughts of committing suicide. The current study could not establish causation and, hence, the need for further studies.

Students who were truant in the current study were more likely to think about committing suicide than students who were not. However, Dunlavy et al. [22] established a negative association between truancy and suicidal ideation. Truancy may be brought by various factors such as bullying, attacks and fights in school. Such factors might deter adolescents from attending school regularly [25]. Therefore, the link between truancy and suicidal thoughts may not be direct and the current study could not establish that.

In the current study, students that reported having been bullied before were more likely to contemplate on committing suicide compared to those who were not. The findings are in tandem with those of Owusu et al. [26] who found a positive association between bullying and suicidal ideation. Bullying tends to traumatise and alienate the victimised adolescents who may think of committing suicide. We also observed that students who were attacked were less likely to consider committing suicide. This is contrary to the finding established by Omigbodun [24]. Attacks may bring negative thoughts about one's life. However, if the frequency of attacks is high, adolescents may not worry so much about the act and not think about committing suicide.

Students that smoked were more likely to ponder over committing suicide than those that did no smoke. This result is similar to what Rudatsikira et al. [23] and Muula et al. [20] reported. Adolescents who indulge in smoking are likely to be stressed and in turn likely to think about committing suicide. Adolescents who abuse substances are likely to be unhealthy (physically and psychological) and should be targeted for intervention to curb suicide.

Our study also established that adolescents who had parental understanding were less likely to cogitate about suicide. The findings from the current study agrees with those of Cash

and Bridge [27] who found that having parental understanding was protective against suicidal ideation. The presence of parents who understand gives children a platform to share problems. Such adolescents are given guidance over issues affecting them and therefore, they are able to withstand life's pressures.

In conclusion, although the prevalence of suicidal ideation among school going adolescents in Pakistan is low, interventions must be put in place to curtail suicidal ideation by considering factors that have been identified in the current study.

ACKNOWLEDGMENTS

We are grateful to the World Health Organization (WHO) and Centres for disease Control and Prevention (CDC) for providing the data for analysis. We also thank the Ministries of Education and Health for the support rendered. Further, we would like to thank all students who participated in the survey.

ABSTRACT

Guyana is the ninth top most suicidal country in the world. A series of Global School-based Health Survey (GSHS) are conducted to monitor trends in the prevalence of health behaviors and establish protective factors among school-going adolescents. Two surveys were conducted in 2014 and 2010. The current study presents results from the second survey conducted in 2010. Weighted logistic regression (univariate or multivariate) analyses were conducted to determine factors associated with suicidal ideation. Unadjusted odds ratios (OR) and adjusted (AOR) together with their 95% confidence intervals (CI) are reported. A total of 2,392 students participated in the survey of which 48.5% were males. Suicidal ideation was reported by 23.5% (16.4% of male and 29.7% of female) participants. Correlates for suicidal ideation were: age, gender (AOR = 0.63, 95% CI [0.61, 0.65]), anxiety (AOR = 1.29, 95% CI [1.24, 1.34]), loneliness (AOR = 1.42, 95% CI [1.37, 1.47]), close friends, truancy, bullied (AOR = 1.36, 95% CI [1.32, 1.40]), attacked (AOR = 1.19, 95% CI [1.16, 1.23]), currently smoked cigarettes, alcohol abuse (AOR = 1.21, 95% CI [1.17, 1.25]), current alcohol use (AOR = 1.22, 95%

* Corresponding Author's Email: ssiziya@gmail.com.

CI [1.18, 1.25]) and parental understanding (AOR = 0.75, 95% CI [0.73, 0.78]). Healthy lifestyles, peer and parental relationships should be promoted in order to avoid suicidal thoughts.

Keywords: suicidal ideation, prevalence, correlates, adolescents, Guyana

INTRODUCTION

Suicide is a major health problem in many countries worldwide [1]. In particular, in Guyana, suicide was the leading cause of death among persons in the age group 15-24 years in the period 2004-2006 [2]. Overall, Guyana has the highest suicide rate in the Caribbean countries and is the ninth top most suicidal country in the world with an incidence of 45 suicides per 100,000 population [3]. The process of ending up with an attempted or complete suicide may start with thinking about committing suicide, planning it and finally executing it. However, this progression may not always hold [4]. An estimate of 60% rate of transition has been observed from suicidal ideation to first suicide attempt within the first year of ideation onset [5]. Another study by Kessler et al. [6] reported the following rates of transition of 34% from ideation to a plan, 72% from a plan to an attempt, and 26% from ideation to an unplanned attempt. Suicidal ideation is a risk factor for complete suicide [7] and it is thus important that efforts are directed to curtailing thoughts about committing suicide by investigating its correlates.

While data is available on suicidal ideation in developed countries, it is limited in developing countries [8, 9], including Guyana. The Global School-based Health Survey (GSHS) was developed by the World Health Organization (WHO) in collaboration with United Nations' UNICEF, UNESCO, and UNAIDS; and with technical assistance from CDC to obtain data on young (aged 13-17 years) people's health behaviour and protective factors for leading causes of morbidity and mortality among children and adults worldwide [10]. Using this survey, trends in the prevalence of health behaviours and protective factors are established for use in evaluation of school health programs [11].

The first Guyana Global School-based Health Survey (GSHS) was conducted in 2004. In this survey, 18.4% of the students (14.9% of males and 21.6% of females) had suicidal ideation [12]. We are not aware of any intervention that was implemented in Guyana since the 2004 GSHS was conducted. However, even in the absence of any intervention, the survey itself may have had an impact on the prevalence of suicidal ideation and its associated factors. It is thus important to keep track of the prevalence of suicidal ideation and its correlates. Moreover, only a limited number of factors were considered in the 2004 analysis of factors associated with suicidal ideation. Furthermore, there is growing literature on the occurrence of suicidal thoughts and its correlates in developing countries: Seychelles, Kenya, Botswana, Namibia, Zimbabwe, Tanzania, and Uganda [12-14] that needs to be updated with new evidence for use in suicide prevention among adolescents.

In line with the GSHS object of tracking the occurrence of mental health situation among the young population, we conducted the current study to determine the current prevalence rate of suicidal ideation and its correlates. We considered more factors in the 2010 that were identified in the growing evidence of factors associated with suicidal ideation than 2004 Guyana GSHS analysis.

Table 1. Variable definition and codes

Variable	Coded	Recoded	Redefined variable
Outcome variable			
During the past 12 months, did you ever seriously consider attempting suicide?	1 = Yes; 2 = No	1 = 1; 2 = 2	Suicidal ideation
Independent variables			
How old are you?	1 = 11 years old or younger; 2 = 12 years old; 3 = 13 years old; 4 = 14 years old; 5 = 15 years old; 6 = 16 years old or older	1-3 = 1; 4 = 2; 5 = 3; 6 = 4	Age
What is your sex?	1 = Male; 2 = Female	1 = 1; 2 = 2	Gender
During the past 30 days, how often did you go hungry because there was not enough food in your home?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2	Food security
During the past 12 months, how often have you been so worried about something that you could not sleep at night?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2	Anxiety
During the past 12 months, how often have you felt lonely?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2	Loneliness
How many close friends do you have?	1 = 0; 2 = 1; 3 = 2; 4 = 3 or more	1 = 1; 2-4 = 2	Close friends
During the past 30 days, on how many days did you miss classes or school without permission?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 or more days	1 = 2; 2-5 = 1	Truancy
During the past 30 days, on how many days were you bullied?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1	Bullied
During the past 12 months, how many times were you physically attacked?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1	Attacked
During the past 12 months, how many times were you in a physical fight?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1	In a fight
During the last 30 days, on how many days did you smoke cigarettes?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1	Currently smoked cigarettes
During the past 30 days, how often did your parents or guardians understand your problems and worries?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	1-3 = 2; 4-5 = 1	Parental understanding
During your life, how many times did you drink so much alcohol that you were really drunk?	1 = 0 times; 2 = 1 or 2 times; 3 = 3 to 9 times; 4 = 10 or more times	1 = 2; 2-4 = 1	Alcohol abuse
During the past 30 days, on how many days did you have at least one drink containing alcohol?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1	Currently used alcohol

METHODS

The 2010 Guyana GSHS was conducted among students in Forms 2, 3, 4, and other. Details of the methodology that was used in the survey are described elsewhere [11]. In summary, the sample was drawn using a two-stage cluster sampling method in which at the first stage of sampling, schools were selected with probability proportional to enrolment size. At stage two of sampling, classes were randomly selected and all students in selected classes were eligible to participate. The overall response rate was 76% with a school response rate of 97% and student response rate of 78%.

A self-administered questionnaire was used to collect the information. The questionnaire included sections on alcohol use, dietary behaviours, hygiene, mental health, physical activity, protective factors, sexual behaviours, tobacco use, violence and unintentional injury. The variables in this study included: age, gender, food security, anxiety, loneliness, close friends, truancy, bullying, being attacked, involvement in a fight, smoking cigarettes, alcohol consumption (use and abuse) and parental understanding as independent variables and suicidal ideation as the outcome variable. Table 1 shows how the variables were originally coded and re-coded.

Logistic regression (univariate or multivariate) analyses were conducted to determine factors associated with suicidal ideation. Unadjusted odds ratios (OR) and adjusted (AOR) together with their 95% confidence intervals (CI) are reported. Analyses were weighted with the following weight to allow results to be generalized to the entire population, not just to those that took part in the survey.

A weighting factor was used in the analysis to reflect the likelihood of sampling each student and to reduce bias by compensating for differing patterns of non-response. The weight used for estimation is given by the following formula:

$$W = W1 \times W2 \times f1 \times f2 \times f3 \times f4$$

where W1 = the inverse of the probability of selecting the school, W2 = the inverse of the probability of selecting the classroom within the school, f1 = a school-level non-response adjustment factor calculated by school size category (small, medium, large), f2 = a class-level non-response adjustment factor calculated for each school, f3 = a student-level non-response adjustment factor calculated by class, and f4 = a post stratification adjustment factor calculated by grade.

RESULTS

A total of 2,392 students participated in the survey of which 48.5% were males. Overall, most of the participants were of age 14 years (30.9%) or 15 years (29.1%). Altogether, 14.2% of the participants were anxious, 17.8% were lonely and 10.4% had no close friends. About a third of the participants reported being truant (33.7%), bullied (37.3%), attacked (39.2%) and involved in a fight (37.7%). In relation to drug use, 12.7% (17.2% of male and 7.6% of female) participants smoked cigarettes and 41.1% (46.5% of male and 35.8% of female)

participants consumed alcohol. Suicidal ideation was reported by 23.5% (16.4% of male and 29.7% of female) participants. These results are shown in Table 2.

¹ unweighted frequencies. ² weighted percents.

Table 3 shows factors associated with suicidal ideation. Food security and involvement in a fight were not significantly associated with suicidal ideation in multivariate analysis. Students aged less than 14 years were more likely to have suicidal thoughts compared to students aged 16 years or older (AOR=1.08, 95% CI [1.03, 1.14]). Compared to female

students, male students were 37% (AOR=0.63, 95% CI [0.61, 0.65]) less likely to have suicidal thoughts.

Anxiety or loneliness were associated with suicidal ideation (AOR=1.29, 95% CI [1.24, 1.34] for anxiety and AOR=1.42, 95% CI [1.37, 1.47] for loneliness). Students who were truant were less likely to have suicidal thoughts (AOR=0.92, 95% CI [0.89, 0.95]).

Being bullied or attacked were significantly associated with suicidal thoughts (AOR=1.36, 95% CI [1.32, 1.40] for being bullied and AOR=1.19, 95% CI [1.16, 1.23] for being attacked). Drug use was associated with suicidal ideation. Students who currently smoked cigarettes were 13% (AOR = 1.13, 95% CI [1.08, 1.18]) more likely to have suicidal thoughts compared to students who did not currently smoke cigarettes. Meanwhile, students who abused alcohol were 21% (AOR = 1.21, 95% CI [1.17, 1.25]) more likely to have suicidal thoughts compared to students who did not abuse alcohol; and students who currently consumed alcohol were 22% (AOR = 1.22, 95% CI [1.18, 1.25]) more likely to have suicidal thoughts compared to students who did not currently consume alcohol.

Students with no close friends were 17% (AOR = 1.17, 95% CI [1.12, 1.23]) more likely to have suicidal thoughts compared to students who had close friends. Students with had parental understanding were 25% (AOR=0.75, 95% CI [0.73, 0.78]) less likely to have suicidal thoughts compared with students who did not have parental understanding.

DISCUSSION

In the current study, suicidal ideation was reported by 23.5% (16.4% of male and 29.7% of female) participants. Factors associated with suicidal ideation included: age, gender, anxiety, loneliness, close friends, truancy, bullied, attacked, smoking, alcohol consumption and parental understanding. The rate of suicidal ideation increased from 18.4% (14.9% among males and 21.6% among females) in 2004 [12] to 23.5% (16.4% of male and 29.7% of female) in 2010, partly due to the effects of the global financial crisis of 2008-2009 [15]. The overall rate of suicidal ideation in the present study of 23.5% compares well with the rates reported in some sub-Saharan African countries [14] of Uganda (19.6%), Botswana (23.1%), Kenya (27.9%) and Zimbabwe (25.5%) but higher than those found in the Seychelles (16%), Tanzania (11.2%), some eastern Asian countries of Thailand, China, Taiwan, Vietnam, and the Philippines [16-19] and in some developed countries of 12.5-16.7% [22, 21]. Variation in rates of suicidal ideation between and within regions of the world may partly be due to differences in coping strategies for depression emanating from life or family events between people of different cultures.

Students of age less than 14 years in the current study were more likely to have suicidal thoughts compared to students who were aged 16 years or older. This finding contradicts that obtained in a 2004 Guyana GSHS in which no significant association was observed between age and suicidal ideation [12]. The difference in the finding from the same population in the two surveys (2004 GSHS and 2010 GSHS) may partly be due to differences in the factors considered in the multivariate analyses. More factors were considered in the analysis of the 2010 GSHS data than in the 2004 GSHS that might have confounded the relationship between age and suicidal thoughts, making the comparison difficult to make. Adolescence is a time of rapid physical, cognitive and emotional growth that is challenging for the adolescent [22]. Younger adolescents (under 15 years of age) may be less likely to cope with the stressors and thought of ending their lives may be a way to escape the experiences. They may not have developed problem solving skills and emotional maturity [9, 23].

Suicidal ideation was more prevalent in females than males (16.4% and 29.7%, respectively) in the present study which contradicts findings of no association between gender

and suicidal ideation in other studies [13, 14]. However, our finding of suicidal ideation being more common in girls than boys is similar to those reported by Lee and Choi [12, 24]. The differences in the relationship between gender and suicidal ideation may indicate gender differences in emotional and behavioural problems [25].

Being anxious or lonely was associated with suicidal ideation in the present study. A similar finding was reported by Rudatsikira et al. [12] in the same study area and Randall et al. [31] who suggested that suicidal behaviour may be a way of expressing distress culturally.

Having close friends and parental understanding were protective factors for suicidal ideation in the present study and in the 2004 Guyana GSHS [12]. In seeking autonomy during the adolescence period, conflicts usually arise between parents and adolescents. Adolescents may turn to their peers for support. It is thus important that healthy adolescent-parent and adolescent-peer relationships are fostered to maintain good mental health.

The current study reports that smokers were more likely to have suicidal thoughts than non-smokers, similar to a finding made by Rudatsikira et al. [12] in the same study area. However, it contradicts the finding by McGee et al. [27] who did not find a significant association between cigarette smoking and suicidal ideation. However, a similar finding to the current study has been reported by Innamorati et al. [28] and Fuller-Thomson et al. [29]. Other studies also found a significant association between smoking and suicidal ideation [30, 31]. In a multinational study, Hockenberry et al. [31] reported an association between tobacco use and suicidal ideation, specifically among girls in Africa. The association between cigarette smoking and suicidal ideation may not be causal because smoking may mediate other psychosocial causes of suicidal ideation such as depression. Adolescents may perceive smoking as a possible solution to stressful events.

Students in the current study who used or abused alcohol were more likely to have suicidal thoughts compared to students who did not use/abuse alcohol. This finding is similar to one obtained by Rudatsikira et al. [12] earlier on in the same population. Another study in three Asian cities of Hanoi, Shanghai and Tapei reported a similar finding that drunkenness is positively associated with suicidal ideation [32]. Curtailing early initiation of alcohol use that has been associated with suicidal ideation [33] could be one of the strategies to prevent suicide.

The association between violent behavior (being bullied or attacked) and suicidal thoughts in the current study may partly be as a result of displacement behavior resulting from stressful events. Violent behavior may be a reaction to stressful events. A similar finding was made by Rudatsikira et al. [12] earlier on in the same study area.

Students who were truant were less likely to have suicidal thoughts in the current study. Students may stay away from school without permission to avoid bullying, for example. Bullying is positively associated with suicidal ideation, and staying away from bullying by skipping school may have a protective effect for suicidal ideation. Skipping school should not be encouraged but efforts should be directed at preventing violence at school.

In conclusion, psychological, behavioral, family and social factors should be considered in designing suicide prevention programs. Healthy lifestyles, peer and parental relationships should be promoted in order to avoid suicidal thoughts.

ABSTRACT

Suicidal ideation is an important factor in completed suicide. There is scarce information on suicidal ideation in developing countries. The objective of the study was to determine correlates for suicidal ideation among adolescents in Samoa. The current study used secondary data obtained in a Global School-based Health Survey (GSHS) which was conducted in Samoa in 2011. Frequencies and logistic regression analyses (bivariate and multivariate) were weighted. Unadjusted odds ratio (OR) and adjusted odds ratio (AOR) together with their 95% confidence intervals (CI) are reported. A total of 2418 students participated in the survey of which 48.4% were males. Suicidal ideation was reported by 33.3% of students (37.8% of males and 29.5% of females). Factors correlated with suicidal ideation were age, gender, food security, loneliness, bullied,

* Corresponding Author's Email: ssiziya@gmail.com.

attacked (AOR = 1.24, 95% CI [1.11, 1.39]), involvement in a fight (AOR = 1.23, 95% CI [1.11, 1.37]), currently smoked cigarettes (AOR = 1.32, 95% CI [1.16, 1.51]), used marijuana (AOR = 1.25, 95% CI [1.09, 1.42]), current alcohol consumption (AOR = 0.76, 95% CI [0.66, 0.88]), alcohol abuse (AOR = 1.53, 95% CI [1.32, 1.76]) and parental understanding. The many factors identified to be associated with suicidal ideation in the current study suggest a multifactor intervention to include social and behavioral factors in curtailing suicidal ideation among adolescents in Samoa.

Keywords: suicidal ideation, prevalence, associated factors, adolescents, Samoa

INTRODUCTION

Suicide rates in populations of the Pacific islands are amongst the highest in the world [1], probably as a result of modernizing social structures [2]. Suicide ideation is an important factor in completed suicide. It is estimated that 60% of persons with suicidal ideation end up with attempted suicide [3]. Other reported transition rates are 34% from suicidal ideation to planning suicide, 72% from planning suicide to attempted suicide, and 26% from suicidal ideation to unplanned attempted suicide [4].

Samoa is located in the Pacific Ocean and its closest islands include American Samoa, Tokelau, Wallis and Futuna, Niue, Fiji and Tonga. There is limited information on suicidal ideation in this region and in Samoa, in particular. In a study of four Pacific island countries in Oceania, the prevalence of suicidal ideation in Samoa (33.8%) was comparable to that of Kiribati (34.7%) but higher than that of Solomon Islands (27.7%) and Vanuatu (17.2%). In all these countries, males had a higher prevalence of suicidal ideation than females; 37.8% of males had suicidal thoughts compared to 29.5% of females [5].

Across the four islands: Samoa, Kiribati, Solomon islands and Vanuatu, current substance use and their initiation (smoking, alcohol use and drug use) were significantly associated with suicidal ideation [5]. It is important to exclusively examine the correlates for suicidal ideation for Samoan school-going adolescents so that interventions to prevent suicidal ideation may be tailored for this population because correlates may be population specific. Furthermore, only a limited number of factors were considered as correlates for suicidal ideation in the study above. The objective of the current study was to determine correlates for suicidal ideation among adolescents in Samoa.

METHODS

The survey was conducted in the Polynesian group of islands known as Samoa that consists of two main islands Upolu and Savai'i and seven smaller islets. Upolu is home to nearly three-quarters of Samoa's population (Figure 1). The population for Samoa was 187,820 in 2011 of which 51.6% were males; 38.3% were aged below 15 years and 80% resided in rural areas [6]. The study was based on secondary data obtained from the 2011 Samoa Global School-based Health Survey (GSHS). The study design was a cross sectional study in which a questionnaire was self-administered to individual students in grades 9-10 in Samoa. Details of the survey have been described elsewhere [7].

Source: https://www.lib.utexas.edu/maps/australia/samoa_rel98.jpg.

Figure 1. Map of Samoa and surrounding countries.

In order to obtain a representative sample of students on the island, students were selected using a two-stage cluster sampling method. During the first stage of sampling, schools were selected with probability proportional to their enrollment size. Classes were then randomly selected during the second stage of sampling and all students in selected classes were eligible to participate. The survey achieved a school response rate of 83%, a student response rate of 96% and an overall response rate of 79%.

Although the survey was run by CDC and WHO, the data set belong to Samoa. However, the data set and code book associated with the core GSHS questionnaire modules were made available to the public two years after the survey was conducted. Only data from core GSHS questions were made public and no school or student identifiers were indicated in the data set.

The questionnaire included questions on alcohol use; dietary behaviors; drug use; hygiene; mental health; physical activity; protective factors; sexual behaviors; tobacco use; and violence and unintentional injury. Responses were made on a computer scannable answer sheet.

Table 1. Global School-Based Health Survey questions used in the analysis of adolescent suicidal ideation

Variable	Question	Coded	Recoded
Dependent variable			
Suicidal ideation	During the past 12 months, did you ever seriously consider attempting suicide?	1 = Yes; 2 = No	1 = Yes; 2 = No
Independent variables			
Age	How old are you?	1 = 11 years old or younger; 2 = 12 years old; 3 = 13 years old; 4 = 14 years old; 5 = 15 years old; 6 = 16 years old or older	1-3 = 1; 4 = 2; 5 = 3; 6 = 4
Gender	What is your sex?	1 = Male; 2 = Female	1 = 1; 2 = 2
Food security	During the past 30 days, how often did you go hungry because there was not enough food in your home?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Anxiety	During the past 12 months, how often have you been so worried about something that you could not sleep at night?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Loneliness	During the past 12 months, how often have you felt lonely?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Close friends	How many close friends do you have?	1 = 0; 2 = 1; 3 = 2; 4 = 3 or more	1 = 1; 2-4 = 2
Truancy	During the past 30 days, on how many days did you miss classes or school without permission?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 or more days	1 = 2; 2-5 = 1
Bullied	Bullied during the past 30 days, on how many days were you bullied?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Attacked	During the past 12 months, how many times were you physically attacked?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1
In a fight	During the past 12 months, how many times were you in a physical fight?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1
Currently smoked cigarettes	During the past 30 days, on how many days did you smoke cigarettes?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Used marijuana	During your life, how many times have you used marijuana (also called bo da)?	1 = 0 times; 2 = 1 or 2 times; 3 = 3 to 9 times; 4 = 10 to 19 times; 5 = 20 or more times	1 = 2; 2-5 = 1
Currently consumed alcohol	During the past 30 days, on how many days did you have at least one drink containing alcohol?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Alcohol abuse	During your life, how many times did you drink so much alcohol that you were really drunk?	1 = 0 times; 2 = 1 or 2 times; 3 = 3 to 9 times; 4 = 10 or more times	1 = 2; 2-4 = 1
Parental understanding	During the past 30 days, how often did your parents or guardians understand your problems and worries?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	1-3 = 2; 4-5 = 1

Data was analyzed using SPSS version 16. The dependent variable was suicidal ideation that was obtained by asking the question ‘During the past 12 months, did you ever seriously consider attempting suicide?’ The dependent and independent variables were recoded as shown in Table 1. Frequencies and logistic regression (bivariate and multivariate) analyses were weighted using the following weighting factor:

$$W = W1 \times W2 \times f1 \times f2 \times f3 \times f4$$

where W1 = the inverse of the probability of selecting the school, W2 = the inverse of the probability of selecting the classroom within the school, f1 = a school-level non-response adjustment factor calculated by school size category (small, medium, large), f2 = a class-level non-response adjustment factor calculated for each school, f3 = a student-level non-response adjustment factor calculated by class, and f4 = a post stratification adjustment factor calculated by grade.

Unadjusted odds ratio (OR) and adjusted odds ratio (AOR) together with their 95% confidence intervals (CI) are reported.

RESULTS

Altogether, 2,418 students participated in the survey of which 48.4% were males. Most (40.4%) of the participants were of age 14 years. About a third of the participants had no food security (36.1%). About 1 in 4 of the students reported anxiety (27.8%) and loneliness (23.1%). Most (83.5%) of the students had close friends. Over half (55.4%) of the students missed school or classes without permission. The majority of students was bullied (74.2%), attacked (71.7%) and involved in a fight (68.3%). Current cigarette smoking was reported by 44.1% of males and 27.0% of females. Similarly, 44.4% of males and 27.1% of females reported using marijuana. Alcohol consumption was also reported by a third of the students (overall 35.9% of students, 45.2% of males and 27.3% of females currently consumed alcohol; 36.6% of all students abused alcohol with 48.0% of males and 26.5% of females having done the same). About a third of the participants had parents who understood their problems and worries. The prevalence of suicidal ideation was 33.3% (37.8% among males and 29.5% among females). These results are shown in Table 2.

Table 3 shows factors associated with suicidal ideation. Students aged 14 years were 22% (AOR=0.78, 95% CI [0.67, 0.90]) less likely to have suicidal ideation than students of age 16 years or older. Other factors associated with suicidal ideation were gender (AOR = 1.14, 95% CI [1.04, 1.25]), food security (AOR = 1.10, 95% CI [1.00, 1.21]) and loneliness (AOR = 1.15, 95% CI [1.03, 1.28]). Violence was associated with suicidal ideation (bullied (AOR = 1.18, 95% CI [1.05, 1.32]), attacked (AOR = 1.24, 95% CI [1.11, 1.39]) and involvement in a fight (AOR = 1.23, 95% CI [1.11, 1.39])). Drug abuse was also associated with suicidal ideation (AOR = 1.32, 95% CI [1.16, 1.51]) for currently smoked cigarettes and AOR = 1.25, 95% CI [1.09, 1.42]) for used marijuana and AOR = 1.53, 95% CI [1.32, 1.76]) for alcohol abuse). Students who drank alcohol were 24% (AOR=0.76, 95% CI [0.66, 0.88]) less likely to have suicidal thoughts compared to students who did not drink alcohol. Students with parental understanding were 19% (AOR = 0.81, 95% CI [0.74, 0.89]) less likely to have suicidal thoughts compared to students who did not have parents who understood their problems and worries.

DISCUSSION

In the current study, age, gender, food security, loneliness, violence (bullied, attacked and involvement in a fight), substance use (smoking cigarettes or marijuana, alcohol consumption and abuse) and parental understanding were significantly associated with suicidal ideation. It is not entirely clear why the age of 14 years was protective, while students aged below this age were at higher risk, suggesting an inconsistency finding. Muula et al. [8] found that

students aged below 14 years were at increased risk for suicidal ideation. Meanwhile, Randall et al. [9], Silva et al. [10] and Sharma et al. [11] found no significant association between age and suicidal ideation. Establishing an association between age and suicidal ideation is important so that age at which to intervene to reduce adolescents having suicidal thoughts could be established. Studies have shown no consistent finding between gender and suicidal ideation, reflecting the different impact of culture on gender. While in the current study females were a higher risk for suicidal ideation than males, similar to what was reported by Garrison et al. [12] and Abel et al. [13], no association was reported by Hallfors et al. [14] and Jorgensen et al. [15]. Contrary, Muula et al. [8] found males to be more likely to have suicidal ideation than females. It was observed that females have a higher rate of depression than males and may explain the higher suicidal ideation prevalence in females than males.

Students who went hungry in the current study because there was not enough food in the home who may also have been lonely were more likely to have suicidal thoughts. Provision of food security may also curtail violence (bullying, physical attacks and fighting) and substance abuse (smoking cigarettes and marijuana and abusing alcohol) in adolescents which have been associated with suicidal ideation [16, 17].

Stress leading to depression as a result of lack of enough food may be an important factor in the occurrence of suicidal ideation. It is, however, interesting that students in the current study who consumed alcohol were less likely to have suicidal ideation. How can alcohol consumption in moderation be protective, while abusing it is a risk for suicidal ideation? This is a research question that should be answered. However, Rossow et al. [18] suggested that substance use may not directly result in suicidal ideation but that it compounds depression to result in suicidal thoughts.

Wagner et al. [19] reported that poor child-parent relationship may cause poor physical and emotional status that may result in suicidal thoughts. Randall et al. [9] also reported that lack of parental support is associated with suicidal ideation. Good parenting involving discussing problems and worries adolescents may be faced with is important in curtailing suicidal ideation.

In conclusion, the many factors identified to be associated with suicidal ideation in the current study suggest the need to have a multifactor intervention to include social and behavioral factors in curtailing suicidal ideation.

ABSTRACT

Adolescent suicidal behavior is a neglected public health issue especially in middle and low-income countries. However, it is an important precursor to later attempted and completed suicide which is of major public health significance. It is in view of this that this work was conducted and the main objective was to determine prevalence and associated factors for suicidal ideation among school-going adolescents in Iraq. Secondary data from the Global School-based Health Survey conducted in 2012 was analyzed. Bivariate and multivariate analyses at 95% confidence interval were conducted to determine factors associated with suicidal ideation. Out of 2027 students, 17.6% (18.0% of males and 17.2% of females) had considered committing suicide. Factors positively significantly related with adolescents' suicidal ideation among Iraq school-going adolescents were male gender, food insecurity, anxiety, loneliness, having no close friends, truancy, history of attack and bullying, having been involved in a fight and current smoking. Parental understanding and age less than 15 years of age were the protective factors against suicidal ideation. Intervention measures to curb the vice should

target peer pressure and build adolescent self-esteem through establishing and advocating for social support networks.

Keywords: suicidal ideation, prevalence, correlates, adolescents, Iraq

INTRODUCTION

Suicidal behavior among school-going adolescents is an important global concern. It is considered to be an important precursor to later attempted and completed suicide and is of major public health significance. Suicide has not been considered as an important area of research in most developing countries. It still remains a neglected issue especially in middle and low-income countries like Iraq [1].

According to the World Health Organization (WHO), nearly one million people commit suicide every year [2]. WHO reports that suicide is a global problem and in 2012, countries in low and middle income regions recorded 75% of global suicide cases. It was estimated in the same year that suicide accounted for 1.4% of all deaths worldwide, making it the 15th leading cause of death [3]. Each year, about 4 million adolescents world-wide attempt suicide and suicide is the third leading cause of death among adolescents [4] and in the 15-24 years age group [5] and the second leading cause of death among college students [6].

Figure 1. Map of Iraq showing its neighbouring countries.

Although the overall rate of suicide among youth has declined slowly since 1992, it is still unacceptably high [7]. A 5.0% prevalence rate of suicidal ideation was obtained in the 2007 Global School-based Health Survey (GSHS) among secondary students in Kut City, Iraq [1]. Interventions targeting suicidal ideation are important because most of suicidal acts start with seriously thinking about how to commit them. A study among secondary school adolescents in Kut city [1] indicated depression, anxiety, poor school grade, and subjection to corporal punishment at home as factors significantly related to adolescents' suicidal behavior (suicidal ideation or attempted suicide). These factors may be biased towards suicidal attempt

because over ninety percent of the students with suicidal behavior attempted suicide [1]. Further, Kut city may not represent the entire country. Furthermore, confounding factors were not adjusted for in the analysis. Clearly, there is need to ascertain factors associated with suicidal ideation in Iraq. Therefore, the objectives of the current study were to determine the prevalence of suicidal ideation and its correlates using the most recent 2012 GSHS.

METHODS

The study setting was Iraq, bordered by Iran, Jordan, Kuwait, Saudi Arabia, Syria, Turkey and a small stretch of the Persian Gulf as shown in Figure 1. Secondary data from the 2012 Global School based Health Survey (GSHS) developed by WHO to provide data on health and social behaviors among the school-going adolescents in Iraq was used in the analysis. The survey measured a number of variables including age, gender, food security, anxiety, loneliness, lack of close friends, truancy, history of attack, bullying, involvement in a fight, current alcohol use, alcohol abuse, marijuana use and parental understanding. The analysis involved the assessment of factors that could be associated with suicidal ideation in this group of adolescents.

The Iraq GSHS was a two-stage cluster sample design, in which in the first stage, schools were selected with probability proportional to enrollment size. In the second stage, classes were randomly selected and all students in selected classes were eligible to participate. Assessments of associations were conducted using both bivariate and multivariate logistic regression analyses at 95% confidence interval.

RESULTS

Out of the 2027 school-going adolescents recruited in the 2012 Global School-based Health Survey, 57.3% were males. Table 1 shows factors that were under consideration and distributed according to gender. The characteristics of the study population included in the analysis showed that 42.7% of adolescents had problems regarding food security (most of the time or always went hungry because there was not enough food in the home). Female adolescents reported anxiety and loneliness more than their male counterparts 18.1% and 20.0% compared with 9.3% and 14.0%, respectively. Only 6.3% adolescents reported having no close friends. Truancy was common among both females (26.7%) and males (31%). Similarly, bullying was common at 24.4% among females and slightly high among males at 32.6%. More male adolescents reported having been attacked (36.3%) compared to females (22.4%) and close to half (46.8%) of male adolescents were involved in a fight compared to 23.6% of female. Reports of current smoking were more common among males at 14.7% compared to 5.3% among female students. Parental understanding was reported as lacking in a lot of female and male students, 38.9% and 42.4% respectively. Close to 1/5th of both male (18.0%) and female (17.2%) students reported having considered suicidal ideation, with an overall prevalence of suicidal ideation of 17.6%.

Factors found to be associated with suicidal ideation among school-going adolescents in Iraq in the 2012 GSHS study are presented in Table 2. Results in the table show that age of adolescents was significantly associated with suicidal ideation; less than 15-year-old adolescents were less likely to have suicidal ideation compared to those who were 16 years or older (AOR = 0.69, 95% CI [0.68, 0.70] for 14 year-olds and AOR = 0.69, 95% CI [0.68, 0.70] for aged less than 14 years). Adolescents aged 15 years were 1.22 times more likely to commit suicide compared to those who were 16 years or older (AOR = 1.22, 95% CI [1.21, 1.23]). Adolescents with food insecurity were 1.07 (95% CI [1.06, 1.08]) times more likely to consider committing suicide compared to those with food security. Anxious adolescents were 50% more likely (AOR = 1.50, 95% CI [1.49, 1.51]) to have suicidal thoughts compared to those who never reported anxiety. Adolescents who reported to have no close friends were 1.29 (95% CI [1.28, 1.31]) times more likely to experience suicidal ideations compared to

those who did not have close friends while lonely respondents were 67% (AOR = 1.67, 95% CI [1.66, 1.68]) more likely to consider committing suicide compared to those who did not report loneliness. Those with a history of having been attacked were 1.15 (95% CI [1.20, 1.22]) times more likely to consider committing suicide compared to those not been attacked before. Having been involved in a fight was 1.12 (95% CI [1.20, 1.22]) times more likely to consider suicide compared to those with no history of having been involved in a fight. Adolescents who reported current smoking were 45% more likely to think of committing suicide (AOR = 1.45, 95% CI [1.44, 1.46]) than nonsmokers. Adolescents with parental understanding were 9% less likely (AOR = 0.91, 95% CI [0.90, 0.91]) to have suicidal ideation compared to students who did not have parental understanding.

DISCUSSION

The current study findings indicate a prevalence of 17.6% of school-going adolescents with suicidal ideation, a finding that is in accord with other similar studies [8, 9]. A number of factors have been negatively and positively associated with suicidal ideation. Young age (less than 15 years) and having parental understanding were negatively associated with suicidal ideation while anxiety, having close friends, loneliness, having been attacked, having been involved in a fight and current smoking were positively associated with suicidal ideation.

Male adolescents were more likely to consider committing suicide compared to females. This is in accord with another study finding which indicated that males are more likely to think of committing suicide compared to females [10]. The explanation could be that female adolescents mature earlier than males in such a way that they are able to cope with the challenges faced during adolescence period.

The findings of our study show that suicidal ideation among school-going adolescents in Iraq is influenced by psycho-social factors such as anxiety and loneliness. Loneliness and anxiety have been found to be significantly associated with suicidal ideation in many other studies [11, 12]. However, we are unable to ascribe causation in the current study because the design was cross sectional. It is possible that because of suicidal ideation, adolescents may tend to be lonely or anxious while thinking about how to commit suicide. Alternatively, because they are lonely or anxious due to other reasons, they may in turn think about committing suicide.

The results of our current study show that adolescents involved in current smoking were significantly more likely to have suicidal ideas compared to those that were not involved in smoking. Other unhealthy behaviors such as been bullied, attacked and involvement in a fight were also significantly associated with suicidal ideation. Adolescents involved in smoking at an early stage usually risk getting involved in other unhealthy behaviors and they are significantly more likely to have suicidal ideation as is the case in another study elsewhere [13].

Having close friends and parental understanding were both significantly associated with suicidal ideation in the present study. Supportive parental relationships have been associated with less suicidal ideation in other cross sectional studies as well [14, 15] and in a longitudinal study [16] and support from friends may decrease the risk of mental health [16].

The findings highlight a number of possible intervention targets for the earliest stage of suicidal ideation similar to previous findings [17] which indicated the need for strengthening a network of social support among students on campus, parents and family. Violence should also be considered in these interventions.

ABSTRACT

Suicidal ideation is a public health concern in many countries. There is need for robust research to establish factors associated with suicidal ideation among in-school adolescents. In Trinidad and Tobago, considerable level of research has been conducted on suicidal ideation among adolescents. However, more research is still needed in order to establish and profile factors associated with suicidal ideation among in-school adolescents. The objective of the study was to determine factors associated with suicidal ideation among in-school adolescents in Trinidad and Tobago. Analysis of the secondary data from the 2011 Trinidad and Tobago Global School-Based Health Survey was conducted using bivariate and multivariate logistic regression at 95% confidence interval. The study recruited a total of 2,811 students. The results showed that the proportion of students who reported suicidal ideation was 16.3% and female (19.3%) students reported a higher ($p < 0.001$) proportion than males (13.3%). Having understanding parents, history of bullying, being of male gender and being 15 years of age were negatively associated with suicidal ideation, while food security, anxiety, lack of close friends,

* Corresponding Author's Email: mulengingo@yahoo.co.uk.

loneliness, history of attack, involvement in a fight, truancy, currently smoking, alcohol abuse, current alcohol use and marijuana use were all positively associated with suicidal ideation. Therefore, issues relating to family and parental support structure, age and gender, violence among peers and substance abuse should be considered when planning and implementing public health intervention programs against suicidal ideation among in-school adolescents in Trinidad and Tobago.

Keywords: suicidal ideation, prevalence, associated factors, adolescents, Trinidad and Tobago

INTRODUCTION

Adolescent suicidal behavior is a major public health concern in many countries, developed and developing alike [1]. Suicide behavior includes suicidal thoughts and suicide attempt. Suicide is a global phenomenon in all regions of the world; statistically, suicidal behavior is the third leading cause of premature death in the adolescent age group [2]. Deaths due to suicide have been estimated to be over 800 000 every year [3] and it is the second leading cause of death in 15-29-year-olds [1]. Suicidal attempts are estimated to range between 2.8% and 13.2% among adolescents [4]. A number of studies have been done and various possible explanations have been suggested for the rising suicide trends, however, a lot still needs to be done [5, 6].

Work to establish trends and rates of suicide have been done worldwide and some analyses still do not present consistent information regarding the causes of death and suicide rates among young people aged 15-19 years [1, 7, 8]. In the Caribbean region suicide is a major public health problem and there are indications that mental health problems are common in the Caribbean and may have a role to play in this health problem [9, 10]. According to previous research [10], Trinidad and Tobago has the second highest suicide rates in the region. Although the rates of suicide are high in the Caribbean, research in this field is still low and speculations are that the paucity of research on suicide in the Caribbean is due to little priority given to the issue by researchers and mental health professionals working within the region. Some researchers attribute this lack of robust research in this area to the sensitive nature that is involved in working with suicidal patients [11]. In Trinidad and Tobago, other than gender, studies on suicide have established a number of other factors associated with suicide. In a study by Hutchinson and Simeon, social distress was noted as an important contributor to the rate of suicide in Trinidad and Tobago, particularly among men [12].

Generally, suicidal behavior predetermines suicides. It is thus important that suicidal behavior is characterized. In a study conducted by Rodriguez and colleagues, social predictors of suicidal behavior in Nicaragua included involvement in family issues and alcohol abuse, other social demographic factors such as education and poverty were not identified as factors associated with suicidal expressions [13]. Other studies have reported low rates of suicidal behavior in African population [11, 14] and this is said to signify a cultural and ethnic difference. Cultural predispositions have been identified as some of the reasons for low rates of suicidal behavior. Certain cultural predispositions such as varying concepts of distress among different population groups for instance concepts of distress among east Indians

involved in suicidal behavior may not be the case among people of African-Caribbean heritage.

One of the suicidal behaviors is suicidal ideation. Some researchers have indicated that there are a number of factors that contribute to suicidal ideation and some of the factors include loss of social cohesion, violence, traditional family structure breakdown, economic instability, lack of employment opportunities, and mental health issues such as rising prevalence of depressive disorders (9, 10, 13]. The factors may vary according to populations within and between countries. Therefore, it is important that studies are conducted to establish factors that may be useful in designing interventions that are population-specific to curtail suicidal thoughts and eventually suicide. Thus, the objectives of the current study were to determine correlates for suicidal ideation including its prevalence among in-school adolescents in Trinidad and Tobago.

METHODS

The study was conducted in the Republic of Trinidad and Tobago, a twin island *country* bordering the Caribbean to the north and sharing maritime boundaries with other *nations*. It is situated off the northeast coast of South America at the extreme southern end of the Lesser Antilles as shown in Figure 1.

Figure 1. Trinidad and Tobago and its surrounding islands and countries.

This chapter presents results of the secondary data analysis obtained from The Global School based Health Survey (GSHS) on health and social behaviors of in-school adolescents in Trinidad and Tobago. The survey measured demographic characteristics of age and gender; social behaviors such as involvement in a fight, truancy, food security, alcohol use and abuse, current smoking in general and use of marijuana, bullying, loneliness, close friendship, anxiety and attack; parental understanding, and the social and health outcome of having considered suicide.

The secondary data was analyzed in order to assess factors that are associated with suicidal ideation among in-school adolescents in Trinidad and Tobago. Assessment of association was conducted through both bi-variate and multivariate logistic regression analysis.

RESULTS

The in-school adolescents aged less 14 years old had the largest proportion of representation (42.9%) in the current study and more than half (54.6%) of the participants were male. Factors under consideration were distributed according to sex as shown in Table 1. The study population features included in the analysis showed that less than 10% of both male and female adolescents had challenges with food security, reported anxiety and lack of close friends. As for loneliness, 11.4% of females reported having experienced loneliness compared to males at 8.2%. More than three quarters of both male (82.0%) and female (79.9%) students practiced truancy. A high proportion of both female (87.9%) and male (82.7%) adolescents were victims of bullying. Majority of male students (40.3%) reported having been attacked compared to females (25.7%). In a similar way, close to half (46.5%) of male students reported having been involved in a fight compared to 26.0% of female students. Reports of current smoking were more common among males at 13.0% compared to 6.2% among female students ($p < 0.001$). Almost a similar proportion of pupils reported lack of parental understanding in female (40.1%) and male students (39.7%). Close to 1/5th of male (19.7%) and slightly more than 1/5th (23.7%) of female students reported having abused alcohol. More than half of both male students (65.6%) and female students (69.0%) reported that they were currently not taking any alcohol and only 10% of male pupils reported using marijuana. Suicidal ideation was reported in 19.3% of female students compared to 13.3% of their male counterparts.

The factors associated with suicidal ideation are presented in Table 2 and results show that age was significantly associated with suicidal ideation, students aged fifteen [15] years were 12% less likely (AOR=0.88, 95% CI [0.84, 0.92]) to have suicidal ideation compared to those aged sixteen years and above. Students aged 14 years and those less than 14 years were 1.07 times (AOR=1.07, 95% CI [1.02, 1.12]) and 1.14 times (AOR=1.14, 95% CI [1.09, 1.20]) more likely to commit suicide compared to students who were 16 years old and above. Male students were 33% more likely to commit suicide compared to female students.

No	1	1

Students with food security problems were 1.28 times more likely (AOR = 1.28, 95% CI [1.22, 1.35]) to consider committing suicide compared to students with food security. Anxious students were 1.54 times more likely (AOR = 1.54, 95% CI [1.48, 1.61]) to have suicidal thoughts compared to students who never reported anxiety. Students who reported not to have close friends were 1.06 times more likely (AOR=1.06, 95% CI [1.01, 1.11]) to experience suicidal ideations compared to students who had close friends while lonely pupils

were 2.04 times more likely (AOR=2.04, 95% CI [1.97, 2.11]) to consider committing suicide compared to students who did not report loneliness. Students having been attacked were 1.27 times more likely (AOR = 1.27, 95% CI [1.24, 1.31]) to consider committing suicide compared to those having not been attacked before. Students who have been involved in a fight were 1.05 times more likely to consider suicide (AOR = 1.05, 95% CI [1.01, 1.08]) compared to those with no history of having been involved in a fight. Respondents who reported current smoking were 1.20 times more likely to think of committing suicide (AOR=1.20, 95% CI [1.14, 1.25]) compared with non-smokers. Students who reported having understanding parents were 37% less likely (AOR = 0.63, 95% CI [0.61, 0.65]) to have suicidal ideation compared to students who did not have parental understanding. Students who reported alcohol abuse were 1.19 times more likely to commit suicide compared to those who did not report alcohol abuse (AOR=1.19, 95% CI [1.16, 1.23]). Respondents who reported current alcohol use were 1.26 times more likely to commit suicide compared to those who did not report current alcohol use (AOR = 1.26, 95% CI [1.22, 1.30]). Students who took marijuana were 1.55 times more likely to commit suicide (AOR = 1.55, 95% CI [1.47, 1.63]) compared to those who did not report use of marijuana.

DISCUSSION

The current study examined the correlates for suicidal ideation among in-school Trinidad and Tobago adolescents using Global School Health Survey data. This study found that 16.3% of in-school adolescents seriously considered committing suicide and this prevalence is consistent with the prevalence of Lebanese adolescents (16%) who thought of committing suicide in a previous study [15]. Having understanding parents, history of bullying, being of male gender and being 15 years of age were negatively associated with suicidal ideation, while food security, anxiety, lack of close friends, loneliness, history of attack, involvement in a fight, truancy, currently smoking, alcohol abuse, current alcohol use and marijuana use were positively associated with suicidal ideation.

Suicidal ideation in younger age is not a common finding in many studies, however, the finding in this study is in accord with the result in another study elsewhere [6] which observed an increase of suicide mortality at a lower age and related it to an early age onset for depressive disorders. In view of this previous finding, it can be assumed that an increase of suicidality at a lower age may indirectly suggest evidence of an early age onset of depressive disorder.

The results of our study show that gender was significantly associated with suicidal ideation and females were more likely to have suicidal ideas compared to male adolescents. This is contradicting the finding by Wasserman et al. [1] in which suicide rates for young people in the 15-19 age group are, as for other age groups, higher in males than in females.

Adolescents who reported food-insufficient were significantly more likely to think of suicide than those that did not have food security challenges. A study among US adolescents [16] agree with this result. The other findings of the current study showed that poor mental health issues such as loneliness, anxiety and no close friends were significantly associated with suicidal ideation. This is reaffirmed by several studies [17, 18] that have shown that suicidal ideation is associated with loneliness and anxiety.

Our study results showed that incidences of victimization significantly increased the likelihood of suicidal ideation among in-school adolescents in Trinidad and Tobago. Similarly, another study [19] elsewhere showed that involvement in fight, attack or bully—victim problems at school, was significantly related to suicidal ideation. Substance abuse was found to be significantly associated with suicidal ideation and a lot of research has been conducted on this subject [14, 20, 21] and most of the results agree with our findings.

In conclusion, the current study indicates the public health importance of highlighting the commonly observed factors associated with this public health problem of suicidal ideation. It is essential to consider unhealthy behaviors such as substance abuse, violent behavior among peers and social support structures as the main determinants of suicidal ideation among in-school adolescents in Trinidad and Tobago. Therefore, parental and social support, age and gender of adolescents should also be considered when planning and implementing public health intervention programs against suicidal ideation among in-school adolescents in Trinidad and Tobago.

ABSTRACT

Suicide rates in Kuwait are on the increase and information on suicidal ideation which may lead to suicide is scanty. The objective of the study was to determine factors that are associated with suicidal ideation. Weighted frequencies to estimate proportions and logistic regression analyses (bivariate and multivariate) to establish significant factors associated with suicidal ideation were conducted using secondary data obtained in a 2011 Kuwait Global School-based Health Survey. Unadjusted odds ratio (OR) and adjusted odds ratio (AOR) together with their 95% confidence intervals (CI) are reported. Of the 2672 students who participated in the survey. Overall, 19.9% (18.7% of male and 21.3% of female) students reported suicidal ideation. Factors associated with suicidal ideation were age, gender (male gender: AOR = 0.75; 95% CI [0.73, 0.78]), food security, anxiety (AOR = 1.43; 95% CI [1.39, 1.46]), loneliness (AOR = 1.61; 95% CI

* Corresponding Author's Email: zyanga70@gmail.com.

[1.57, 1.65]), close friends (AOR = 1.33; 95% CI [1.24, 1.42]), truancy (AOR = 1.20; 95% CI [1.17, 1.23]), bullied (AOR = 1.54; 95% CI [1.50, 1.58]), attacked, in a fight (AOR = 1.39; 95% CI [1.35, 1.43]), currently smoked cigarettes, used marijuana (AOR = 1.84; 95% CI [1.73, 1.95]) and parental understanding (AOR = 0.70; 95% CI [0.68, 0.72]). The prevalence of suicidal ideation in Kuwait among adolescents is high. Suicidal ideation is prevalent in Kuwait. Interventions designed using the factors identified in the current study are needed to curb the rate of suicidal thoughts.

Keywords: suicidal ideation, prevalence, associated factors, adolescents, Kuwait

INTRODUCTION

Suicide rates in Kuwait increased from 3.2 in 2002 to 6.1 per 100,000 population in 2010 [1]. While not all suicidal thoughts materialize in suicide, prevention of suicidal ideation may curtail suicide rates. Information on suicidal ideation among adolescents is scanty in Kuwait and in the region as a whole partly due to the illegality of suicide. El-Sayed Badr [2] obtained a prevalence rate of suicidal ideation of 20.0% among participants in a 2010 Kuwait Global School-based Student Health Survey. Factors associated with suicidal behaviours (ideation, planning and attempts) in that study were gender, smoking, physical violence, loneliness, bullying and parental understanding. Literature suggests that more factors are associated with suicidal ideation. These include: age [3-5], food security [6-9], anxiety [7, 10-14], having close friends [15-17], truancy [10, 18], attacked [7, 11, 19] and involvement in a fight [7, 20, 21]. The current study aimed to further determine factors that are associated with suicidal ideation.

METHODS

Kuwait is a high income country located in the Middle East and North Africa region [22]. Preliminary results of the 2011 census indicated a population of 3.1 million of which 65% was non-national and about 83% of the total population resided in the capital, Kuwait city [23]. This high level of non-nationals poses a challenge to estimate the population size for Kuwait because the Kuwait government rarely grants citizenship to foreigners. Kuwait borders with Iraq and Saudi Arabia (Figure 1). About a quarter (25.3%) of the population is aged below 15 years [23]. The study population comprised school-going adolescents in grades 8 to 10, country-wide. The study design was cross sectional.

A total of 2,672 students participated in the 2011 Kuwait Global School-based Health Survey (GSHS) resulting in a school response rate of 97%, the student response rate of 88%, and an overall response rate of 85%.

A two stage cluster sampling method was used to select participants for a sample that is representative of school going adolescents mainly in the age group 13-15 years. The school was the sampling unit in the first stage of sampling. Schools were randomly selected proportional to their enrolment size. In the second stage of sampling, classes were then randomly selected and all students in selected schools were eligible to participate in the study irrespective of their ages.

Figure 1. Map of Kuwait and its neighbouring countries.

The 2011 Kuwait GSHS questionnaire had the following sections: dietary behaviours; drug use; hygiene; mental health; physical activity; protective factors; tobacco use; and violence and unintentional injury. Table 1 shows variables that were considered in the analysis. The dependent variable was suicidal ideation, while the independent variables were age, gender, food security, anxiety, loneliness, close friends, truancy, bullied, attached, in a fight, smoking cigarettes/marijuana and parental understanding.

Data Analysis

Data was analysed using SPSS version 16. Frequencies and logistic regression analyses were weighted using the following equation:

$$W = W1 \times W2 \times f1 \times f2 \times f3 \times f4$$

where W1 = the inverse of the probability of selecting the school, W2 = the inverse of the probability of selecting the classroom within the school,

f1 = a school-level non-response adjustment factor calculated by school size category (small, medium, large), f2 = a class-level non-response adjustment factor calculated for each school, f3 = a student-level non-response adjustment factor calculated by class, and f4 = a post stratification adjustment factor calculated by grade.

Table 1. Global School-Based Health Survey questions used in the analysis of adolescent suicidal ideation

Variable	Question	Coded	Recoded
Dependent variable			
Suicidal ideation	During the past 12 months, did you ever seriously consider attempting suicide?	1 = Yes; 2 = No	1 = Yes; 2 = No
Independent variables			
Age	How old are you?	1 = 11 years old or younger; 2 = 12 years old; 3 = 13 years old; 4 = 14 years old; 5 = 15 years old; 6 = 16 years old or older	1-3 = 1; 4 = 2; 5 = 3; 6 = 4
Gender	What is your sex?	1 = Male; 2 = Female	1 = 1; 2 = 2
Food security	During the past 30 days, how often did you go hungry because there was not enough food in your home?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Anxiety	During the past 12 months, how often have you been so worried about something that you could not sleep at night?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Loneliness	During the past 12 months, how often have you felt lonely?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Close friends	How many close friends do you have?	1 = 0; 2 = 1; 3 = 2; 4 = 3 or more	1 = 1; 2-4 = 2
Truancy	During the past 30 days, on how many days did you miss classes or school without permission?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 or more days	1 = 2; 2-5 = 1
Bullied	Bullied during the past 30 days, on how many days were you bullied?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Attacked	During the past 12 months, how many times were you physically attacked?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1
In a fight	During the past 12 months, how many times were you in a physical fight?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1
Currently smoked cigarettes	During the past 30 days, on how many days did you smoke cigarettes?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Used marijuana	During your life, how many times have you used marijuana (also called khushkhash)?	1 = 0 times; 2 = 1 or 2 times; 3 = 3 to 9 times; 4 = 10 to 19 times; 5 = 20 or more times	1 = 2; 2-5 = 1
Parental understanding	During the past 30 days, how often did your parents or guardians understand your problems and worries?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	1-3 = 2; 4-5 = 1

RESULTS

Of the 2,672 students who participated in the survey, 52.3% were males and 87.2% were aged less than 16 years. Overall, 9.3% of the students reported that they had no food security. About 1 in 5 students reported being anxious (20.2%) and lonely (18.7%). Most (96.7%) of the students had close friends. Overall, 57.9% of the students (53.8% of males and 62.2% of females) missed school or classes without permission. Violence was common ($p < 0.001$) among males than females (bullied: 36.2% males and 19.6% females; attacked: 41.3% males and 24.8% females; in a fight: 59.9% males and 28.6% females). Cigarette smoking was reported by 26.0% of males and 8.2% of females. Meanwhile, marijuana was used by 5.7% of males and 0.4% of females. Altogether, 39.3% of students indicated that their parents understood their problems and worries. About 1 in 5 of the students reported that they had suicidal thoughts: 18.7% of males and 21.3% of females with an overall rate of 19.9%. These results are shown in Table 2.

Correlates for suicidal ideation are shown in Table 3. All the factors considered in the analysis were significantly associated with suicidal ideation in both bivariate and multivariate analyses. While students aged 14 years (AOR = 1.20; 95% CI [1.15, 1.24]) were more likely to have suicidal ideation, those of age 15 years were less likely to have suicidal thoughts (AOR = 0.75; 95% CI [0.72, 0.78]) compared with students of age 16 years or older. Male students were 25% (AOR = 0.75; 95% CI [0.73, 0.78]) less likely to have suicidal ideation compared with female students. Students from homes that had no food security were 6% (AOR = 1.06; 95% CI [1.02, 1.10]) more likely to have suicidal ideation compared with students from homes with food security.

Compared with students who were not anxious, students who were anxious were 43% more likely to have suicidal ideation (AOR = 1.43; 95% CI [1.39, 1.46]). Meanwhile, students who were lonely were 1.61 (95% CI [1.57, 1.65]) times more likely to have suicidal thoughts compared with students who were not lonely. Students who had no close friends were 33% (AOR = 1.33; 95% CI [1.24, 1.42]) more likely to have suicidal thought compared with students who had close friends. Missing school or classes was positively associated with suicidal ideation (AOR = 1.20; 95% CI [1.17, 1.23]).

Violence was associated with suicidal ideation. Students who were bullied were 54% (AOR=1.54; 95% CI [1.50, 1.58]) more likely to have suicidal ideation compared with students who were not bullied. Compared with students who were not attacked, students who were attacked were 9% (AOR=1.09; 95% CI [1.06, 1.12]) more likely to have suicidal thoughts. Involvement in a fight was associated with suicidal thoughts (AOR = 1.39; 95% CI [1.35, 1.43]).

Smoking was significantly associated with suicidal thoughts. Compared with students who did not smoke cigarettes, students who smoked cigarettes were more likely to have suicidal ideation (AOR = 1.18; 95% CI [1.13, 1.21]). Students who used marijuana were 84% (AOR=1.84; 95% CI [1.73, 1.95]) more likely to have suicidal thoughts than students who did not use marijuana. Students who had parental understanding were 30% less likely to have suicidal ideation (AOR=0.70; 95% CI [0.68, 0.72]) than those without.

Table 2. Distribution of factors considered in the analysis by gender among junior high school students in Kuwait, 2011

Factor	Total n ¹ (%) ²	Males n ¹ (%) ²	Females n ¹ (%) ²

DISCUSSION

In the current study, prevalence rate of suicidal ideation of 19.9% overall (18.7% among males and 21.3% among females) was observed. Factors associated with suicidal ideation were age, gender, food security, anxiety, loneliness, close friends, truancy, bullied, attacked, involvement in a fight, smoking (cigarettes or marijuana) and parental understanding. Using

the same data set and methods of data analysis, the prevalence rate of suicidal ideation in the current study was 19.9% as opposed to 20.0% reported by El-Sayed Badr [2]. It is possible that the difference is due to rounding off error.

Findings on demographic factors associated with suicidal ideation have not been consistent. In the current study, while students aged 14 years were more likely to have suicidal thoughts, students aged 15 years were less likely to have suicidal ideation compared with students of age 16 years or older, contradicting the notion that younger adolescents may be less likely to cope with the stressors. In another study by Rudatsikira et al. [16], no association was observed between age and suicidal ideation.

Male students were less likely to have suicidal ideation compared with females in the present study. This finding accords those of Rudatsikira et al. [16] and Lee and Choi [24]. However, no association was observed between gender and suicidal ideation in other studies [25, 26]. Differences in the association between gender and suicidal ideation are partly a reflection in gender differences in emotional and behavioural reactions [27] in different cultures.

Adolescents in homes with not enough food were more likely to have suicidal ideation in the current study. Lack of enough food may trigger anxiety and loneliness that have been associated with suicidal ideation in adolescents. Similar findings have been reported by Rudatsikira et al. [16] and Hockenberry et al. [28].

In the current study, violence (bullied, attacked or fighting) has been associated with suicidal thoughts. Rudatsikira et al. [16] observed that students in Guyana who were bullied were more likely to have suicidal ideation compared with students who were not bullied. Because of fear of being bullied, attacked or involved in a fight, school going adolescents may miss classes or school without permission. Prevention of violence should be addressed at school.

Apart from McGee et al. [29] who did not find a significant association between smoking and suicidal ideation, most studies have reported a significant association between smoking and suicidal ideation [16, 28, 30-32]. Smoking marijuana was also significantly associated with suicidal ideation in the current study. Smoking (cigarettes or marijuana) may mediate depression in its association with suicidal ideation and students may perceive smoking as a way out of their stressful situations.

Good relationships with friends and parents are important so that any negative changes in the adolescents can be identified and addressed before situations become unmanageable.

In conclusion, suicidal ideation in Kuwait is prevalent and interventions utilizing information obtained in the current study should be designed to curtail the rate of suicidal ideation.

ABSTRACT

There is scanty information on suicide in general and in particular suicide ideation in Fiji. Fijian Indians have one of the highest rates of suicide in the world. The objectives of the study were to determine the rate of suicide ideation and its correlates among adolescents in Fiji. Secondary data obtained in a 2010 Fiji Global School-based Health Survey was used in the analysis. Weighted frequencies to estimate proportions and logistic regression analyses (bivariate and multivariate) to establish significant factors associated with suicidal ideation were conducted. Unadjusted odds ratio (OR) and adjusted odds ratio (AOR) together with their 95% confidence intervals (CI) are reported. A total of 1673 students participated in the survey. Overall, 17.6% (16.4% of male and 18.5% of female) students reported suicidal ideation. Factors associated with suicidal ideation were age, gender (male gender: AOR = 0.75; 95% CI [0.73, 0.77]), food security, anxiety (AOR = 1.46; 95% CI [1.41, 1.51]), loneliness (AOR = 1.26; 95% CI

* Corresponding Author's Email: zyanga70@gmail.com.

[1.21, 1.31]), bullied, attacked (AOR = 1.28, 95% CI [1.24, 1.32]), in a fight (AOR = 1.23; 95% CI [1.19, 1.27]), smoking cigarettes (AOR = 1.39, 95% CI [1.34, 1.45]) and alcohol use (AOR = 1.41, 95% CI [1.36, 1.46]). The prevalence of suicidal ideation in Fiji is of concern and efforts should be made to design interventions that may lower the prevalence, considering the information obtained in the current study.

Keywords: suicidal ideation, prevalence, correlates, adolescents, Fiji

INTRODUCTION

Fiji is one of the happiest countries in the world with 93% of people indicating as such [1] despite unstable political past and only in 2006 were democratic elections held [2]. Fiji has a tight-knit society that is mostly village based with the extended family, where children are cared for by the community; and there is low crime rate [3]. Fiji is located in the South Pacific Ocean with more than 300 islands of which 110 are permanently inhabited [4]. Although the overall suicide rate for Fiji was 19 per 100,000, the suicide rate for Fijian Indians aged 15-24 years of 34 per 100,000 population was higher than those for other countries in the world in 1982-1983 [5, 6]. In 2014, Fiji with a rate of 7.50 per 100,000 population ranked 100 out of 172 countries in suicide in 2014 [7]. Clearly, there are unhappy faces in the happiest country in the world.

There is limited information on suicidal ideation in Fiji. A prevalence of suicidal ideation and related behaviors was reported to be 22.5% among ethnic Fijian adolescent girls in Fiji [8]. In order to contribute to the body of knowledge on suicide ideation, a study was conducted to determine the extent of the problem and establish factors associated with it.

METHODS

Fiji is a developing country in the upper middle income group [9] located in the East Asia and Pacific region (Figure 1). The population of Fiji at the time of the survey was 860,559 in 2010 [10] and it is now 905,949 consisting of 51% Fijian, 44% Indian and 5% others. The 0-14 years age group makes up 31.1% of the population. In terms of religion, 52% of the population is Christian, 38% Hindu, 8% Muslim and 2% belong to other regions or are none believers [11]. The study population comprised school-going adolescents in Forms 2, 3 and 4 in Fiji nation-wide [12].

A cross sectional study was conducted in which 1,673 students participated in the 2010 Fiji Global School-based Health Survey (GSHS) resulting in a school response rate of 100%, the student response rate of 90%, and an overall response rate of 90%.

A two stage cluster sampling technique was used to select participants for a sample that is representative of students in Forms 2, 3 and 4 in Fiji. The school was the primary sampling unit that was selected with probability proportional to enrolment size. The second stage of sampling involved randomly selecting classes in the selected schools and all students in the selected classes were eligible to participate in the survey.

Figure 1. Fiji islands.

The questionnaire that was used in the 2010 Fiji GSHS had the following sections: alcohol use, dietary behaviours; mental health, physical activity, sexual behaviour, tobacco use, and violence and unintentional injury. Table 1 shows variables that were considered in the analysis. The dependent variable was suicidal ideation, while the independent variables were age, gender, food security, anxiety, loneliness, close friends, bullied, attached, in a fight, cigarette smoking and alcohol use/abuse.

Data Analysis

Data was analysed using SPSS version 16. Frequencies and logistic regression analyses were weighted using the following equation:

$$W = W1 \times W2 \times f1 \times f2 \times f3 \times f4$$

where $W1$ = the inverse of the probability of selecting the school, $W2$ = the inverse of the probability of selecting the classroom within the school, $f1$ = a school-level non-response adjustment factor calculated by school size category (small, medium, large), $f2$ = a class-level non-response adjustment factor calculated for each school, $f3$ = a student-level non-response adjustment factor calculated by class, and $f4$ = a post stratification adjustment factor calculated by grade.

Table 1. Variable definition and codes

Variable	Coded	Recoded	Redefined variable
Outcome variable			
During the past 12 months, did you ever seriously consider attempting suicide?	1 = Yes; 2 = No	1 = 1; 2 = 2	Suicidal ideation
Independent variables			
How old are you?	1 = 11 years old or younger; 2 = 12 years old; 3 = 13 years old; 4 = 14 years old; 5 = 15 years old; 6 = 16 years old or older	1-3 = 1; 4 = 2; 5 = 3; 6 = 4	Age
What is your sex?	1 = Male; 2 = Female	1 = 1; 2 = 2	Gender
During the past 30 days, how often did you go hungry because there was not enough food in your home?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2	Food security
During the past 12 months, how often have you been so worried about something that you could not sleep at night?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2	Anxiety
During the past 12 months, how often have you felt lonely?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2	Loneliness
How many close friends do you have?	1 = 0; 2 = 1; 3 = 2; 4 = 3 or more	1 = 1; 2-4 = 2	Close friends
During the past 30 days, on how many days were you bullied?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1	Bullied
During the past 12 months, how many times were you physically attacked?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1	Attacked
During the past 12 months, how many times were you in a physical fight?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1	In a fight
During the last 30 days, on how many days did you smoke cigarettes?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1	Cigarette smoking
During your life, how many times did you drink so much alcohol that you were really drunk?	1 = 0 times; 2 = 1 or 2 times; 3 = 3 to 9 times; 4 = 10 or more times	1 = 2; 2-4 = 1	Alcohol abuse
During the past 30 days, on how many days did you have at least one drink containing alcohol?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1	Alcohol use

RESULTS

Of the 1,673 students who participated in the survey, 49.8% were males and 11.1% were aged 16 years or older. Overall, 10.7% of the students reported that they had no food security. Less than 3 in 20 students reported being anxious (14.0%) and lonely (12.3%). Most (93.1%) of the students had close friends. Overall, 43.0% of the students were bullied. Physical attack and fighting were more common ($p < 0.001$) in males than females (attacked: 52.1% males and 39.6% females; in a fight: 60.2% males and 36.6% females). Cigarette smoking was reported by 18.1% of males and 7.9% of females.

Meanwhile, alcohol abuse was reported by 19.2% of males and 8.2% of females; alcohol use by 22.1% of males and 11.2% of females. Suicide ideation was reported by 17.6% of students (16.4% of males and 18.5% of females). These results are shown in Table 2.

Correlates for suicidal ideation are shown in table 3. While students aged 14 years (AOR = 1.12; 95% CI [1.07, 1.17]) were more likely to have suicidal ideation, those of age <14 years were less likely to have suicidal thoughts (AOR = 0.84; 95% CI [0.80, 0.89]) compared with students of age 16 years or older. Male students were 25% (AOR = 0.75; 95% CI [0.73, 0.77]) less likely to have suicidal ideation compared with female students.

Students from homes that had no food security were 6% (AOR = 1.06; 95% CI [1.01, 1.10]) more likely to have suicidal ideation compared with students from homes with food security. Compared with students who were not anxious, students who were anxious were 46% (AOR = 1.46; 95% CI [1.41, 1.51]) more likely to have suicidal ideation. Meanwhile, students who were lonely were 1.26 (95% CI [1.21, 1.31]) times more likely to have suicidal thoughts compared with students who were not lonely.

Violence was associated with suicidal ideation. Students who were bullied were 16% (AOR=1.16; 95% CI [1.13, 1.19]) more likely to have suicidal ideation compared with students who were not bullied. Compared with students who were not attacked, students who were attacked were 28% (AOR = 1.28; 95% CI [1.24, 1.32]) more likely to have suicidal thoughts. Involvement in a fight was associated with suicidal thoughts (AOR = 1.23; 95% CI [1.19, 1.27]).

Smoking was significantly associated with suicidal thoughts. Compared with students who did not smoke cigarettes, students who smoked cigarettes were more likely to have suicidal ideation (AOR = 1.39; 95% CI [1.34, 1.45]). Students who consumed alcohol were 41% (AOR = 1.41; 95% CI [1.36, 1.46]) more likely to have suicidal thoughts than students who did not consume alcohol.

DISCUSSION

The prevalence rate of suicidal ideation in the current study was 17.6% overall (16.4% among males and 18.5% among females). Factors associated with suicidal ideation were age, gender, food security, anxiety, loneliness, bullied, attacked, involvement in a fight, cigarette smoking and alcohol use. In the present study, while students aged 14 years were more likely to have suicidal thoughts, students aged <14 years were less likely to have suicidal ideation compared with students of age 16 years or older, contradicting the finding by Rudatsikira et al. [13] who reported no association between age and suicidal ideation. The inconsistencies in the finding on the relationship between age suicide ideation suggest further research.

The finding that males were less likely to have suicidal thoughts accords the findings by Rudatsikira et al. [13] and Lee and Choi [14]. Contrary, no significant association was observed between gender and suicidal ideation in other studies [15, 16]. Differences in the association between gender and suicidal ideation are partly a reflection of cultural influence on gender roles which differ between populations.

Food security was associated with suicidal thoughts in the current study and so was anxiety and loneliness. Because of lack of enough food homes, adolescents may be anxious for where to find the next meal and in the process become lonely. Rudatsikira et al. [13] and

Hockenberry et al. [17] also reported similar findings. Further analysis to establish interactions among factors associated with suicidal ideation is suggested.

In the current study, being bullied, attacked or involved in fighting were associated with suicidal ideation. Rudatsikira et al. [13] observed a similar finding in Guyana. Prevention of violence at school may reduce the prevalence of suicidal thoughts.

Smoking cigarettes and consuming alcohol were positively associated with suicidal ideation in the current study. Other studies [13, 17-19] have reported similar findings. However, McGee et al. [20] did not find a significant association between smoking and suicidal ideation.

No	1	1

Alcohol consumption was also associated with suicidal ideation in the present study. Kandel et al. [21] and Swanson et al. [22] have also reported similar findings. Adolescents may perceive cigarette smoking and consumption of alcohol as a way to get rid of stress that may lead to suicidal thoughts. Because the study design was a cross section, we can not ascribe causation. Further research utilizing higher study designs are recommended.

In conclusion, the prevalence of suicidal ideation in Fiji is of concern and efforts should be made to design interventions that may lower the prevalence, considering the information obtained in the current study.

ABSTRACT

Although suicide rates appear to be lower in Muslim populations than in those of other religions, it is important that interventions are identified and put in place before the rates reach unmanageable levels. Suicidal ideation among adolescents is one such area that can be targeted to curtail suicide rates. The objectives of the study were to determine the prevalence and correlates for suicidal ideation among school-going Arab adolescents in the West Bank Judea and Samaria). Secondary data obtained in a 2010 West Bank Global School Health Survey was used in the study. Weighted analyses were conducted to obtain weighted frequencies, unadjusted odds ratios (OR), adjusted odds ratios (AOR) and their 95% confidence intervals (CI). The survey recruited 1908 students of which 50.7% were females. About 1 in 4 of the students (overall 23.7%; Males 25.8% and Females 21.8%) ever seriously considered attempting suicide. The following factors were significantly associated with suicidal ideation: age gender, food security 1.51 (95% CI [1.45, 1.56]), anxiety (AOR = 1.25; 95% CI [1.21, 1.28]), loneliness (AOR = 1.62; 95% CI [1.57, 1.67]), having close friends (AOR = 1.54, 95% CI [1.48, 1.61]), truant, bullied

* Corresponding Author's Email: zyanga70@gmail.com.

(AOR = 1.26; 95% CI [1.23, 1.30]), physically attacked, involvement in a fight, smoking cigarettes (AOR = 1.35; 95% CI [1.31, 1.39]) and parental understanding. Suicidal ideation in the West Bank is prevalent among adolescents. In designing interventions for prevention of suicidal ideation, the following should be considered: prevention of violence in form of bullying, physical attack and fighting, encouraging socialization and discouraging smoking.

Keywords: suicidal ideation, prevalence, associated factors, adolescents, West Bank

INTRODUCTION

The worldwide suicide rate is estimated at 11.6 per 100,000 inhabitants [1]. An act of suicide may be preceded by suicidal thoughts, planning for suicide and suicidal attempt. Intervention should, thus, be targeted at an earlier stage of suicidal thoughts. Suicidal ideation may be influenced by social, economic, cultural, political and geographic factors [2]. The West Bank (Judea and Samaria) has been at war, exposing adolescents to destructive and violent events, and also to personal losses; self-destructive behaviours; exposure to suicide of other people; and access to means to complete suicide [3]. Suicide in the Middle East cannot be explained by Islam, a religion that is predominant in the region. The Quran prohibits taking away own life. Quran 4:29-30 says

“... nor kill yourself: for verily God hath been to you Most Merciful! If any do that in rancor and injustice, soon shall He cast them into the Fire: And easy it is for God.”

This is for the Arab population, but in fact the Jewish Torah also prohibit suicide. Hence, the low suicide rates in the region may be due to underreporting because suicide is prohibited by the Quran. However, despite the possible underreporting, Lester [4] argued that suicide rates appear to be lower in Muslims than in those of other religions. Another possible consequence for this prohibition is the scarcity of information on suicide in the Arab West Bank.

A study conducted in the East Mediterranean Region (EMR) in Jordan, Lebanon, Morocco and United Arab Emirates reported suicidal ideation rates of 24.7%, 19.6%, 17.8% and 16.2%, respectively [5]. Factors associated with suicidal ideation in the EMR varied across the four countries. While gender was not associated with suicidal ideation in Jordan and UAE, males were less likely to have suicidal ideation than females in Lebanon and Morocco. Age was only significantly associated with suicidal ideation in Lebanon with students less than 15 years being less likely to have suicidal thoughts. Only bullying, no friendship and feeling sad were consistently associated with suicidal ideation across the four countries. It is, hence, important that correlates for suicidal ideation are established to inform interventions for each country. The objectives for the current study were to determine prevalence and correlates for suicidal ideation among adolescents in the West Bank.

METHODS

The study population comprised of Arab students in grades 7th, 8th, and 9th in the West Bank. Arab West Bank with a population of about 2 million and a growth rate of 3.4% [6] (see Figure 1). The population comprises of 45% children under the age of 15 years. Thirty percent of the population is refugee and 27% of these refugees live in refugee camps [7]. Study is cross sectional.

Table 1. Global School-Based Health Survey questions used in the analysis of adolescent suicidal ideation

Variable	Question	Coded	Recorded
Dependent variable			
Suicidal ideation	During the past 12 months, did you ever seriously consider attempting suicide?	1 = Yes; 2 = No	1 = Yes; 2 = No
Independent variables			
Age	How old are you?	1 = 11 years old or younger; 2 = 12 years old; 3 = 13 years old; 4 = 14 years old; 5 = 15 years old; 6 = 16 years old or older	1-3 = 1; 4 = 2; 5 = 3; 6 = 4
Gender	What is your sex?	1 = Male; 2 = Female	1 = 1; 2 = 2
Food security	During the past 30 days, how often did you go hungry because there was not enough food in your home?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Anxiety	During the past 12 months, how often have you been so worried about something that you could not sleep at night?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Loneliness	During the past 12 months, how often have you felt lonely?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Close friends	How many close friends do you have?	1 = 0; 2 = 1; 3 = 2; 4 = 3 or more	1 = 1; 2-4 = 2
Truancy	During the past 30 days, on how many days did you miss classes or school without permission?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 or more days	1 = 2; 2-5 = 1
Bullied	Bullied during the past 30 days, on how many days were you bullied?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Attacked	During the past 12 months, how many times were you physically attacked?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1
In a fight	During the past 12 months, how many times were you in a physical fight?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1

Variable	Question	Coded	Recorded
Currently smoked cigarettes	During the past 30 days, on how many days did you smoke cigarettes?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Parental understanding	During the past 30 days, how often did your parents or guardians understand your problems and worries?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	1-3 = 2; 4-5 = 1
Marijuana	During your life, how many times have you used marijuana (also called khushkhash)?	1 = 0 times; 2 = 1 or 2 times; 3 = 3 to 9 times; 4 = 10 to 19 times; 5 = 20 or more times	1 = 2; 2-5 = 1

A total of 1,908 students participated in the West Bank GSHS resulting in a school response rate of 100%, the student response rate of 94%, and an overall response rate of 94%. A two stage cluster sampling method was used to draw the sample. The primary sampling unit was the school. Schools were randomly selected proportional to their enrolment size. Classes were then randomly selected. All students in selected schools were eligible to participate in the study.

The 2010 West Bank GSHS questionnaire comprised of modules on dietary behaviours; drug use; hygiene; mental health; physical activity; protective factors; tobacco use; and violence and unintentional injury. Table 1 shows variables that were considered in the current study. The dependent variable was suicidal ideation, while the independent factors were age, gender, food security, anxiety, loneliness, close friends, truancy, bullied, attached, in a fight, currently smoked cigarettes and parental understanding.

Data Analysis

Data was analysed using SPSS version 16. Frequencies and logistic regression analyses were weighted using the following weighting factor:

$$W = W1 \times W2 \times f1 \times f2 \times f3 \times f4$$

where $W1$ = the inverse of the probability of selecting the school, $W2$ = the inverse of the probability of selecting the classroom within the school,

$f1$ = a school-level non-response adjustment factor calculated by school size category (small, medium, large),

$f2$ = a class-level non-response adjustment factor calculated for each school,

$f3$ = a student-level non-response adjustment factor calculated by class, and

$f4$ = a post stratification adjustment factor calculated by grade.

RESULTS

The survey recruited 1,908 students of which 50.7% were females. Females tended to be younger than males with 35.5% of males aged <14 years compared to 43.5% of females in the same age group. Overall, 9.2% of the students reported that most of the time or always they went hungry because there was not enough food in the home. The proportions of students who indicated that they felt lonely and anxious were 13.4% and 16.0%, respectively. Overall, 7.4% of the students reported that they had no close friends. About a third (34.1%) of the students was truant. Altogether, 53.3% of students were bullied. Significantly more male (50.1%) than females (27.1%) students were attacked. Similarly, 67.0% of male and 26.1% of female students were involved in a fight ($p < 0.001$). Regarding smoking, significantly more male (32.7%) than female (8.4%) students smoked cigarettes ($p < 0.001$). Significantly ($p < 0.001$) more female (43.3%) than male (33.9%) students indicated that their parents or guardians understood their problems and worries. About 1 in 4 of the students (overall 23.7%; Males 25.8% and Females 21.8%) ever seriously considered attempting suicide. These results are shown in Table 2.

Factors that were associated with suicidal ideation are shown in Table 3. All the factors that were considered in the analysis were significantly associated with suicidal ideation at both bivariate and multivariate logistic regression analysis. As a result of the effect of confounding, the association between gender and suicidal ideation changed from males being more likely to have suicidal ideation at bivariate analysis to less likely to have suicidal ideation in multivariate analysis. The directions of associations for the rest of the variables remained the same.

Students of ages 14 (AOR = 0.89; 95% CI [0.85, 0.93]) or 15 (AOR = 0.93; 95% CI [0.88, 0.97]) years were less likely to have suicidal ideation compared to those aged 16 years or older. Male students were 13% (AOR = 0.87; 95% CI [0.85, 0.90]) less likely to have suicidal ideation compared with female students.

Students without food security were 1.51 (95% CI [1.45, 1.56]) times more likely to have suicidal ideation compared with students who had enough food in their homes. Compared to students who were not anxious or lonely, students with anxiety or those who were lonely were 25% (AOR = 1.25; 95% CI [1.21, 1.28]) and 62% (AOR = 1.62; 95% CI [1.57, 1.67]), respectively, more likely to have suicidal ideation. When compared with students who had close friends, students who did not have close friends were 1.54 (95% CI [1.48, 1.61]) times more likely to have suicidal ideation.

Truant students were 10% (AOR = 1.10; 95% CI [1.07, 1.13]) more likely to have suicidal ideation compared with students who did not miss classes or school without permission. Students who were bullied were 26% (AOR = 1.26; 95% CI [1.23, 1.30]) more likely to have suicidal ideation compared with students who were not bullied. Students who were physically attacked were 1.19 (95% CI [1.17, 1.22]) times more likely to have suicidal ideation compared to students who were not attacked. Similarly, students who were involved in a fight were 12% (AOR = 1.12; 95% CI [1.09, 1.15]) more likely to have suicidal ideation compared with students who were not involved in a fight.

Students who smoked cigarettes were 35% (AOR = 1.35; 95% CI [1.31, 1.39]) more likely to have suicidal ideation compared with non-smokers. Compared with students with parents or guardians who did not understand their problems and worries, students with

understanding parents or guardians were 17% (AOR = 0.83; 95% CI [0.81, 0.85]) less likely to have suicidal ideation.

DISCUSSION

Suicidal ideation was prevalent in the Arab West Bank with 23.7% (25.8% of males and 21.8% of females) reporting it. All the factors considered in the study were significantly associated with suicidal ideation; i.e., age, gender, food security, anxiety, loneliness, close friends, truancy, bullied, attacked, involvement in a fight, smoking cigarettes and parental understanding. The rate of suicidal ideation obtained in the Arab West Bank is similar to those reported by Khalid [5] of 24.7% in Jordan, 19.6% in Lebanon, 17.8% in Morocco and 16.2% in United Arab Emirates.

Students in the current study aged 14 or 15 years were less likely to have suicidal ideation compared with students aged 16 years or older. This finding contradicts findings in Jordan, Morocco and UAE where no significant association was observed between age and suicidal ideation [5] in Jordan (24.7%) and Lebanon (19.6%). Further, in Lebanon, students aged <15 years were less likely to have suicidal thoughts compared with students who were aged 16 years or older. Further research is suggested to determine which age groups are risk factors for suicidal ideation so that tailored interventions may be targeted to the at risk age groups. The relationship between gender and suicidal ideation has not been consistent in the region. While males were less likely to have suicidal ideation than females in Lebanon and Morocco, no association was observed between gender and suicidal ideation in Jordan and UAE. The finding from the current study suggests that males were less likely to have suicidal thoughts than females. Generally, there is evidence from this region that males may be less likely to have suicidal thoughts than females. Abel et al. [8] argued that females are at higher risk for suicidal ideation because females have a higher rate of depression than males.

Hunger or family food insufficiency has been associated with psychosocial outcomes and suicide symptoms, respectively [9, 10], and it is no wonder that students who had no food security were more likely to have suicidal thoughts in the current study.

Students who have no close friends are more likely to be socially isolated, feel lonely, anxious and depressed. Anxiety, loneliness and depression have been associated with suicidal ideation [11-13]. The findings from the current study support these findings. Lack of parental understanding of the problems or worries facing adolescents has been associated with suicidal ideation in the current and previous study [13]. It is important that adolescents receive social support to avoid suicidal thoughts.

Truancy may be linked to bullying, being attacked and involvement in a fight. Students may be truant in fear of being bullied, attacked or involved in a fight. These factors have been associated with suicidal thoughts in the current study and accord findings from other studies. King et al. [14] reported a significant association between physical fighting and suicidal ideation. Bullying was associated with suicidal ideation by Brunstein et al. [15]. Bullied students are rejected by their peers and stressed [16, 17] and can result in depression that is associated with suicidal ideation. Truancy has been associated with suicidal ideation in the current study. This finding accords that of D'Aulerio et al. [18].

Smoking has been associated with suicidal ideation in the current study. Similar findings have been reported before [19-23]. Students may smoke when they are depressed. Hence, smoking may not be directly associated with suicidal thoughts. Alternatively, students with suicidal thoughts may smoke as they think about how to end their lives. Because the study design was cross sectional, we cannot ascribe caution to the observed associations.

In conclusion, suicidal ideation in the Arab West Bank is prevalent among adolescents. In designing interventions for prevention of suicidal ideation, the following should be considered: prevention of violence in form of bullying, physical attack and fighting, encouraging socialization and discouraging smoking.

ABSTRACT

Suicidal behaviour is still of major public health significance among the younger generation despite some research work indicating that there has been a dramatic decrease in the youth suicide rate during the past decade. The objective of the current study was to determine the prevalence of suicidal ideation and associated factors among the in-school adolescents in Morocco. The Moroccan 2010 Global School-based Health Survey (GSHS) data was analyzed using bivariate and multivariate logistic regression analyses at 95% confidence interval. The prevalence of suicidal ideation in Morocco among in-school adolescents was 16.6% (13.9% among males and 20.0% among females) and was positively associated with increase in age (being 15 years or older), issues of food insecurity, anxiety, lack of close friends and loneliness, victimization – attack, bullying; substance abuse – cigarette smoking and use of marijuana. Being male and presence of parental understanding were negatively associated with suicidal ideation. These results underscore the need to provide effective public health intervention programs in Morocco

among in-school adolescents that target issues of substance abuse and address parental/social support in general.

Keywords: suicidal ideation, prevalence, associated factors, adolescents, Morocco

INTRODUCTION

Suicidal behaviour is one of the major causes of injury and mortality globally. It is considered to be an important precursor to later attempted and completed suicide [1]. World Health Organization (WHO) estimates that by the year 2020 about 1.53 million people will die from suicide and about 10-20 times more people will attempt to commit suicide worldwide. If the current trends estimated by WHO continues, it is estimated that on average, there will be one death every 20 seconds and one suicide attempt every 1-2 seconds [2]. While WHO reports that the African region has almost no data available on suicide, countries of the European region submit suicide data to WHO on regular basis [2]. However, according to the crude estimates for suicide in Africa, there are over 34,000 suicides in a year, giving an overall incidence rate of 3.2 per 100,000 population [3]. These figures may be underestimating the extent of the problem of suicides in Africa because deaths that result from suicide are misclassified as an accident or another cause of death to avoid familial, religious and social stigmatizations [4] or as a taboo [1].

Suicidal behaviour is still of major public health significance among the younger generation despite some research work indicating that there has been a dramatic decrease in the youth suicide rate during the past decade [5]. It is ranked third among the leading causes of mortality among 15-to-24 year olds and second among college students [6, 7]. Despite suicide being such an important public health concern among the younger generation, there is still a paucity of data on suicidal ideation in many African countries. In the past years suicidal ideation was not considered as a common issue, however recent research has shown that it actually accounts for a significant public health burden [8]. So far the research work done in African countries such as Uganda, South Africa, Zambia and Nigeria indicate that the challenges faced by suicidal ideation cannot be ignored and the problem is relatively common in this region [9]. Therefore, the study aimed to determine the prevalence of in-school adolescent suicidal ideation and associated factors in Morocco.

METHODS

The Global School-based Health Survey (GSHS) for Morocco was conducted among in-school adolescents. Morocco is located in the southern Mediterranean zone, in the extreme northwest of the African continent as shown in Figure 1. The secondary analysis of the GSHS data on health and social behaviors of students was carried out using bivariate and multivariate logistic regression analyses at 95% confidence interval. The demographic characteristics of age and gender; social behaviours such as involvement in a fight, truancy, food security, alcohol use and abuse, current smoking in general and use of marijuana,

bullying, loneliness, close friendship, anxiety and attack; parental understanding, and the social and health outcome of having considered suicide were considered in the analyses.

Source: http://farm5.static.flickr.com/4107/5023100732_93c26d3914.jpg.

Figure 1. Map of Morocco and its neighbouring countries.

Data representative of all students was produced using a two-stage cluster sampling design. Schools were selected with probability proportional to enrollment size at the first stage. At the second stage, random selection was employed to select classes and as long as students belonged to selected classes, they were eligible to participate. The response rate was 100% for school and 92% for students with an overall response rate of 92%.

RESULTS

Altogether 2,924 students participated in the survey. Table 1 shows the distribution of factors considered in the analysis by gender among the in-school adolescents in Morocco in 2010. There were more female participants (52.3%) and the majority (43.4%) of the participants was 14 years old or younger. Less than 20% of pupils reported food insecurity (10.6%), anxiety (15.5%), having no close friends (8.9%), currently smoking (6.7%) and marijuana use (3.5%). However, 23.1% of female pupils reported loneliness compared to only 13.8% of male pupils ($p < 0.001$). Truancy was reported in 42.1% of male pupils compared to 29.7% of females ($p < 0.001$). Involvement in a fight, being attacked was highly reported among male students at 56.6% and 35.7% respectively compared to 24.5% and 21.7% among females respectively, ($p < 0.001$). Bullying was reported in 21% of female students and only

17.5 % of males reported having been bullied. Parental understanding was lacking in 30.7% of females compared to 24.7% of males, while 20.0% of females had considered committing suicide compared to 13.9% of males. The overall suicidal ideation prevalence was 16.6%.

Table 2 shows factors associated with suicidal ideation among in-school adolescents in Morocco, 2010 GSHS study. Age of students was significantly associated with suicidal ideation. Students aged less than 14 years old were 25% less likely (AOR = 0.75, 95% CI [0.74, 0.76]) while those aged 14 years old were 16% less likely (AOR = 0.84, 95% CI [0.83, 0.85]) to consider committing suicide compared to those aged 16 years or older. On the contrary, students aged 15 years were 1.17 times more likely to consider committing commit suicide compared to students who were aged 16 years or older (AOR = 1.17, 95% CI [1.16, 1.19]). Male participants were 27% less likely (AOR = 0.73, 95% CI [0.72, 0.73]) to have suicidal ideation compared to female students. Students who reported food insecurity were 1.06 times more likely (AOR = 1.06, 95% CI [1.05, 1.07]) to have suicidal ideation compared to students with no food security problems. Anxious students were 1.29 times more likely

(AOR = 1.29, 95% CI [1.28, 1.30]) to have suicidal thoughts compared to students who never reported anxiety. Students without close friends were 1.26 times more likely (AOR = 1.26, 95% CI [1.25, 1.28]) to experience suicidal ideations compared to students with close friends and lonely students were 1.34 times more likely (AOR = 1.34, 95% CI [1.33, 1.35]) to consider committing suicide compared to students who did not report loneliness. Students reported attacks were 1.19 times more likely (AOR = 1.19, 95% CI [1.80, 1.20]) to consider committing suicide compared to those who did not report attacks. Students with an experience of a fight were 5% less likely (AOR = 0.95, 95% CI [0.95, 0.96]) to consider committing suicide compared to those no experience of a fight. Bullied students were 1.36 times more likely (AOR = 1.36, 95% CI [1.35, 1.37]) to think of committing suicide compared to students who were not bullied. Students who reported currently smoking (AOR = 1.44, 95% CI [1.42, 1.46]) and using marijuana (AOR = 1.52, 95% CI [1.50, 1.55]) were 1.44 and 1.52 times, respectively, more likely to consider committing suicide compared to those who did not smoke with cigarettes or marijuana. Students with understanding parents were 15% less likely (AOR = 0.85, 95% CI [0.84, 0.85]) to have suicidal ideation compared to students who did not have parental understanding.

DISCUSSION

The prevalence of suicidal ideation in the current study was high at 16.6%. This prevalence is in accord with results of many other studies, for example, by Zarrouq et al. [1]. However it is not in agreement with what Moroccans believe in and this could be a possible drop in religious ethics and religiosity among Moroccans since suicide is considered as a taboo and a disgraceful act prohibited by religion, condemned by society, and hampered by legal consequences [4].

The factors that were positively associated with suicidal ideation included older age group, female gender, food insecurity, anxiety, lacking close friends and loneliness, history of attack, and bullying; cigarette smoking and use of marijuana. Meanwhile, involvement in a fight and a finding that males were less likely to have suicidal thoughts compared to females have been reported elsewhere [10, 11]. The younger adolescents in the current study were less likely to experience suicidal thoughts possibly because adolescents tend to have exposure to other risk behaviors such as substance abuse as they grow and interact more with peers.

Loneliness and lack of close friends have been significantly associated with suicidal ideation in the current study. The study by Stravynski and Boyer [12] also revealed that the prevalence of suicidal ideation increased with the degree of loneliness. However, it is not clear whether loneliness and lack of close friend may have resulted in suicidal thoughts or vice versa since causation is not implied in a cross sectional study. Anxiety among in-school adolescents in Morocco has also been significantly associated with suicidal ideation. Results of another study elsewhere [13] generally supports the conclusion that anxiety disorders convey risk for suicidal ideation.

Violent behaviors defined as bullying, attacks and fights among peers have been observed to be significantly associated with suicidal thoughts among adolescents in the present study. Adolescents who were involved in a fight or been attacked or bullied were more likely to think of committing suicide compared to those that did not experience such violence. Similarly, findings in other research [14, 15, 16] indicate that violent behaviors such

as fight, bullying and attack are significantly associated with suicidal ideation. It is more likely that students experiencing violence may be more likely to think that it is not worthy live than the converse that suicidal thoughts may be resulting in violence.

The other major factor associated with suicidal thoughts according to the current study is substance abuse. Adolescents who reported cigarette smoking and marijuana were more likely to have suicidal ideas compared to non-smokers. This result is not different from the findings of other studies [9, 17, 18]. Further, low parental monitoring has associated with increased risk of suicidal ideation [18]. Hence, effective public health intervention programs in Morocco among in-school adolescents should consider substance abuse and address parental/social support in ascertaining components of suicide prevention programs are effective in order to optimize use of limited resources.

ABSTRACT

Literature is scant on suicidal behaviours and their correlates in developing countries, including Vietnam. The objectives of the study were to estimate the suicidal ideation rate and determine its associated factors. Proportions of exposure factors were estimated using weighted frequencies and logistic regression analyses (bivariate and multivariate) were weighted to establish significant factors associated with suicidal ideation. Unadjusted odds ratio (OR) and adjusted odds ratio (AOR) together with their 95% confidence intervals (CI) are reported. Altogether, 3331 students participated in the survey. Overall, 16.9% (12.2% of male and 21.1% of female) students reported suicidal ideation. Factors associated with suicidal ideation were age, gender (male gender: AOR = 0.64; 95% CI [0.63, 0.64]), food security (no food security: AOR = 0.68; 95% CI [0.67, 0.69]), loneliness (AOR = 1.82; 95% CI [1.81, 1.83]), close friends (no close friends: AOR = 1.65; 95% CI [1.64, 1.66]), truancy, bullied, attacked, in a fight (AOR = 1.22; 95% CI [1.21, 1.22]), currently smoked cigarettes (AOR = 1.40; 95% CI [1.39, 1.41]), used marijuana (AOR = 0.73; 95% CI [0.72, 0.74]), currently consumed alcohol, alcohol

abuse (AOR = 1.45; 95% CI [1.45, 1.46]) and parental understanding (AOR = 0.70; 95% CI [0.70, 0.71]). The prevalence of suicidal ideation in Kuwait among adolescents is high. The suicidal ideation rate in Vietnam is of concern. Interventions should be designed using information obtained in this study and implemented to lower the rate of suicidal thoughts.

Keywords: suicidal ideation, prevalence, associated factors, adolescents, Vietnam

INTRODUCTION

Suicidal ideation is thought about engaging in behaviour intended to end one's life [1]. It is thinking about, considering, or planning suicide [2] without suicidal actions such as attempted and completed suicide. These thoughts come about when it seems there is no other way but suicide to solve problems and end the pain. Literature on suicidal ideation is abundant in developed countries but limited in developing countries, including Vietnam a middle-income country.

In a study to determine the prevalence of suicidal ideation/attempts and socio-demographic correlates of suicidality among 15-24 year-olds in Vietnam, China, and Taiwan, Blum et al. [3] found a rate of suicidal ideation of 2.3% in Hanoi, Vietnam. Nguyen et al. [4] studying 15-19 year-olds found that 26.3% of the students reported that they had seriously considered attempting suicide. The above rates of suicidal ideation are higher than the reported rate among medical students in years 1, 3 and 5 throughout Vietnam of 8.7% [5]. In other national population based surveys, the prevalence of suicidal ideation was 5.3% in the first survey conducted in 2003-2004 and 12.2% in the second survey conducted in 2009-2010 among adolescents in Vietnam [6].

The correlates for suicidal ideation across the three countries: Vietnam, China, and Taiwan [3] were female gender, younger age, family structure, parental support, family history of suicide, migration status and substance use. Nguyen et al. [4] found the following factors to be associated with suicidal ideation: anxiety, depression, gender, alcohol, abused by parents/other adults, having a tutor after school, seriously quarreled with teachers or other staff and school type. The above studies were not standardized and comparing the results across the studies may not be valid. CDC and WHO designed a Global School-based Health Survey (GSHS) which would make it possible to compare the findings across the surveys in different regions of the world and countries. Some of the factors in the GSHS have not been considered in the above studies. Hence, the objectives of the study were to determine the prevalence and associated factors for suicidal ideation among adolescents in Vietnam that would be comparable with findings from similarly designed surveys.

METHODS

Vietnam became a middle-income country in 2011 from being one of the poorest countries 25 years ago [7]. Estimates suggest that Vietnam was the 14th most populous country in the world with a population of 92.5 million in 2014 [8]. About a quarter of the population (23.1%) was aged less than 15 years [9]. Two thirds (66%) of the population lived

in rural areas [10]. The study population comprised school-going adolescents in grades 8-12 country-wide in Kuwait. The study design was cross sectional. A total of 3,331 students participated in the 2011 Vietnam GSHS resulting in a school response rate of 100%, the student response rate of 96%, and an overall response rate of 96%.

Figure 1. Map of Vietnam with its neighbouring countries.

Table 1. Global School-Based Health Survey questions used in the analysis of adolescent suicidal ideation

Variable	Question	Coded	Recoded
Dependent variable			
Suicidal ideation	During the past 12 months, did you ever seriously consider attempting suicide?	1 = Yes; 2 = No	1 = Yes; 2 = No
Independent variables			
Age	How old are you?	1 = 11 years old or younger; 2 = 12 years old; 3 = 13 years old; 4 = 14 years old; 5 = 15 years old; 6 = 16 years old or older	1-3 = 1; 4 = 2; 5 = 3; 6 = 4
Gender	What is your sex?	1 = Male; 2 = Female	1 = 1; 2 = 2
Food security	During the past 30 days, how often did you go hungry because there was not enough food in your home?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Loneliness	During the past 12 months, how often have you felt lonely?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	4-5 = 1; 1-3 = 2
Close friends	How many close friends do you have?	1 = 0; 2 = 1; 3 = 2; 4 = 3 or more	1 = 1; 2-4 = 2
Truancy	During the past 30 days, on how many days did you miss classes or school without permission?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 or more days	1 = 2; 2-5 = 1
Bullied	Bullied during the past 30 days, on how many days were you bullied?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Attacked	During the past 12 months, how many times were you physically attacked?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1
In a fight	During the past 12 months, how many times were you in a physical fight?	1 = 0 times; 2 = 1 time; 3 = 2 or 3 times; 4 = 4 or 5 times; 5 = 6 or 7 times; 6 = 8 or 9 times; 7 = 10 or 11 times; 8 = 12 or more times	1 = 2; 2-8 = 1
Currently smoked cigarettes	During the past 30 days, on how many days did you smoke cigarettes?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Used marijuana	During your life, how many times have you used marijuana (also called bo da)?	1 = 0 times; 2 = 1 or 2 times; 3 = 3 to 9 times; 4 = 10 to 19 times; 5 = 20 or more times	1 = 2; 2-5 = 1
Currently consumed alcohol	During the past 30 days, on how many days did you have at least one drink containing alcohol?	1 = 0 days; 2 = 1 or 2 days; 3 = 3 to 5 days; 4 = 6 to 9 days; 5 = 10 to 19 days; 6 = 20 to 29 days; 7 = All 30 days	1 = 2; 2-7 = 1
Alcohol abuse	During your life, how many times did you drink so much alcohol that you were really drunk?	1 = 0 times; 2 = 1 or 2 times; 3 = 3 to 9 times; 4 = 10 or more times	1 = 2; 2-4 = 1
Parental understanding	During the past 30 days, how often did your parents or guardians understand your problems and worries?	1 = Never; 2 = Rarely; 3 = Sometimes; 4 = Most of the time; 5 = Always	1-3 = 2; 4-5 = 1

A three stage cluster sampling method was used to select participants for a sample that is representative of school going adolescents mainly in the age group 13-17 years. A province was a primary sampling unit that was selected with probability proportional to school enrolment size. Selection of schools then followed. Schools were also selected with probability proportion to school enrolment size. At the final stage of sampling, classes were randomly selected and all students in selected classes were eligible to participate in the survey.

The 2013 Vietnam GSHS questionnaire was divided into the following sections: dietary behaviours; drug use; hygiene; mental health; physical activity; protective factors; tobacco use; and violence and unintentional injury. Table 1 shows variables that were considered in the analysis. The dependent variable was suicidal ideation, while the independent variables were age, gender, food security, loneliness, close friends, truancy, bullied, attached, in a fight, currently smoked cigarettes, used marijuana, currently consumed alcohol, alcohol abuse and parental understanding.

Data Analysis

Data was analysed using SPSS version 16. Frequencies and logistic regression analyses were weighted. Unadjusted odds ratio (OR) and adjusted odds ratio (AOR) together with their 95% confidence intervals are reported.

RESULTS

Of the 3,331 students who participated in the survey, 46.9% were males. Only 1.1% of the students reported that they had no food security. Overall, 11.5% of the students indicated that they were lonely, 5.5% reported that they had no close friends and 19.4% reported that they missed classes or school without permission. About 1 in 5 students reported violence: bullied (22.7%), attacked (20.9%) and involved in a fight (16.6%). Regarding smoking, 4.7% of the students currently smoked cigarettes and 0.6% used marijuana. Alcohol consumption was reported by a quarter of the students (current consumption of alcohol: 24.9% overall, 33.2% of males and 17.6% of females; alcohol abuse: 22.5% overall, 30.8% of males and 15.3% of females). Overall, 30.4% of students reported that parents understood their problems and worries. These results are shown in Table 2.

Correlates for suicidal ideation are shown in Table 3. All the factors considered in the analysis were significantly associated with suicidal ideation in both bivariate and multivariate analyses. Students aged less than 16 years (AOR = 0.87; 95% CI [0.86, 0.87]) were less likely to have suicidal ideation compared with students of age 16 years or older. Male students were 34% (AOR = 0.64; 95% CI [0.63, 0.64]) less likely to have suicidal ideation compared with female students. Students from homes that had no food security were 32% (AOR = 0.68; 95% CI [0.67, 0.69]) less likely to have suicidal ideation compared with students from homes with food security.

Students who were lonely were 1.82 (95% CI [1.81, 1.83]) times more likely to have suicidal thoughts compared with students who were not lonely. Students who had no close

friends were 65% (AOR = 1.65; 95% CI [1.64, 1.66]) more likely to have suicidal thought compared with students who had close friends. Missing school or classes was positively associated with suicidal ideation (AOR = 1.05; 95% CI [1.05, 1.05]).

No	1	1

Violence was associated with suicidal ideation. Students who were bullied were 18% (AOR = 1.18; 95% CI [1.18, 1.19]) more likely to have suicidal ideation compared with students who were not bullied. Surprisingly, being attacked was negatively associated with suicidal thoughts (AOR = 0.98; 95% CI [0.98, 0.98]). Students who were involved in a fight were 22% (AOR = 1.22; 95% CI [1.21, 1.22]) more likely to have suicidal thoughts compared with students who were not involved in a fight.

Smoking was significantly associated with suicidal thoughts. Compared with students who did not smoke cigarettes, students who smoked cigarettes were more likely to have suicidal ideation (AOR = 1.40; 95% CI [1.39, 1.41]). Interestingly, students who used marijuana were 27% (AOR = 0.73; 95% CI [0.72, 0.74]) less likely to have suicidal thoughts than students who did not use marijuana. Alcohol consumption was positively associated with suicidal ideation (AOR = 1.11; 95% CI [1.10, 1.11]) for currently consumed alcohol and AOR = 1.45; 95% CI [1.45, 1.46]) for alcohol abuse).

Students who had parental understanding were 30% (AOR = 0.70; 95% CI [0.70, 0.71]) less likely to have suicidal ideation compared with students who did not have understanding parents.

DISCUSSION

Suicidal ideation in the current study was reported by 16.9% (12.2% of male and 21.1% of female) respondents. The following factors were associated with suicidal ideation: age, gender, food security, loneliness, close friends, truancy, bullied, attacked, involved in a fight, smoking (cigarettes or marijuana) alcohol (use or abuse) and parental understanding. Students younger than 16 years were less likely to have suicidal ideation compared with students who were of age 16 years or older, contradicting the argument by Muula et al. [11] and Spirito et al. [12] that they are more likely to have suicidal thoughts than the older ones partly because they have not developed problem solving skills and emotional maturity to handle stressful events. The finding that male students were less likely to have suicidal thoughts suggests that males and females are at different developmental stages in relation to how to handle stress and its resultant, depression. Females mature earlier than males and may be more likely to have suicidal thoughts than males in the same age group.

While lack of food security was associated with suicidal thoughts in other studies [13], the finding in the current study that students from homes with no food security were less likely to have suicidal thoughts is interesting. The observed relationship between food security and suicidal ideation in the current study could partly have been due to the effects of school feeding program.

Students who were lonely, had no friends or without parental understanding were more likely to have suicidal ideation. Social interaction is important in relieving stress and subsequently avoiding depression that is associated with suicidal ideation. Generally, studies have shown that loneliness [15, 16], having no close friends [11, 14, 15] and lack of parental understanding [16] are associated with suicidal ideation.

Students who were bullied, attacked or were involved in a fight might also have been truant. All these factors were associated with suicidal ideation in the current study and in other studies [17-19]. Targeting violence in interventions to reduce rates of suicidal ideation rates may in turn curtail suicide rates.

Interventions targeting substance use among adolescents, in particular discouraging students from smoking cigarettes or marijuana and consuming alcohol or abusing it, would help in curtailing suicidal thoughts and in turn reduce suicidal rates. Rudatsikira et al. [14] also found that alcohol abuse is associated with suicidal ideation. Adolescents may perceive substance use/abuse as a reliever of pain.

In conclusion, the suicidal ideation rate in Vietnam is of concern and interventions should be designed and implemented to lower the rate. In designing interventions, the factors established in the study should be considered.

ABSTRACT

The study examined the prevalence of suicidal ideation and associated factors among junior high school students aged 13-15 years in 2012, in Bolivia. Both bivariate and multivariate logistic regression analyses at 95% confidence level were conducted to assess the association between relevant predictor variables and suicidal ideation within the previous twelve months to the survey. A total of 3,477 junior high school students responded to the question on suicidal ideation among other questions in a structured questionnaire from the Global School-based Student Health Survey (GSHS). Overall, 18.2% of the students (13.2% of males and 23.5% of females) reported having had suicidal ideation in the previous 12 months. Significant factors associated with suicidal ideation were: being anxious, lonely, having no close friends, being bullied, being physically attacked or involved in a physical fight, smoking cigarettes or marijuana, alcohol consumption and abuse, and parental understanding. Interventions that address issues of violence against students, fighting with peers, initiation of smoking, alcohol and

* Corresponding Author's Email: enjunju@yahoo.com.

illicit drug use and those that encourage supportive roles of parents and peers may reduce the risk of suicidal ideation.

Keywords: suicidal ideation, prevalence, risk factors, Bolivia

INTRODUCTION

Adolescent suicide and suicidal behaviour have become major public health issues in recent years [1]. Suicide is widely recognized as major cause of mortality in young people and non-fatal suicidal behaviours in young people are associated with considerable morbidity. Suicidal behaviour in adolescence covers a wide spectrum of phenomena [1]. Rates of suicide increase markedly from childhood into adolescence representing a significant public health concern [2].

Suicide, in general, is a global public concern as more than 800,000 people commit it every year and for every suicide there are many more who attempt it [3]. A prior suicide attempt is the single most important risk factor for suicide in the general population [3]. In 2012, suicide was the second leading cause of death among 15-29 year olds worldwide and occurs throughout the life span [3, 4]. In a global burden of disease study, it was estimated that suicide contributes to 6% of all deaths among young people aged 10-24 years worldwide [5, 6]. Notably, 75% of global suicides occur in low and middle income countries [3, 4].

Previously, suicide rates were found to be low in Latin American countries, but that was expected to change [7]. In Bolivia, in a study conducted by analysing data from four different sources between 2007 and 2012, it was found out that more females attempted suicide whereas more males realized it and suicide attempts were most numerous among adolescents in contrast to suicides being most prevalent in the older age groups [8]. In Brazil, a neighbouring country to Bolivia, suicide rates among children and adolescents were reported to be relatively low compared with other countries before 2000 [9].

Although not all suicidal ideation materialize into suicide attempts or suicide, it is the first step on the path to suicide [10-12]. Suicidal ideation is a common mental health problem. The lifetime prevalence of suicidal ideation in Western countries has been reported to be around 10% [1, 2]. In Brazil, the prevalence of suicidal ideation was observed to be 14% and it was associated with violent behaviour, smoking and alcohol consumption [9].

A 60% rate of transition has been observed from suicidal ideation to first suicide attempt within the first year of ideation onset [12]. Suicidal thoughts are preventable with timely and low cost interventions [13]. To date, several environmental, psychological and behavioural factors have been found to be associated with suicidal ideation [14]. Physical, sexual and emotional abuses have been associated with adolescent suicidal ideation [14-16]. Family problems, social pressure, economic struggle, racism and violence, introduce constant emotional stresses and challenges among Peruvian adolescents [17], and these may be associated with suicidal ideation. While there have been reports on the prevalence and correlates of suicidal ideation in the developed world, data from the developing world is limited [10]. In order to contribute to the body of knowledge on suicidal ideation in developing countries, this study was conducted to determine the prevalence and identify associated factors for suicidal ideation.

METHODS

Bolivia is a landlocked country in South America. Brazil forms its eastern border; its other neighbours are Peru and Chile on the west and Argentina and Paraguay on the south (see Figure 1).

The Global School-based Health Survey (GSHS) was developed by the World Health Organization (WHO) in collaboration with UNICEF, UNESCO and UNAIDS with technical assistance from Centers for Diseases Control and Prevention, Atlanta, Georgia, United States with the aim of providing data on health and social behaviours among school-going adolescent students. This paper presents results of a secondary analysis of the data obtained from the GSHS conducted in 2012 among the junior high school students in Bolivia. The survey obtained data on alcohol use; dietary behaviours; drug use; hygiene; mental health; physical activity; protective factors; sexual behaviours; tobacco use; violence and unintentional injury.

The Bolivia GSHS was a two-stage cluster sample design, in which for the first stage, schools were selected with probability proportional to enrolment size. In the second stage, classes were randomly selected and all students in selected classes were eligible to participate. The school response rate was 99%, the student response rate was 89% and the overall response rate was 88%.

Students self-reported their responses to each question on a computer-scannable answer sheet. Variables that were used for our analysis included socio-demographic characteristics, having considered suicide, smoking, loneliness, parental understanding, involvement in a fight, truancy, anxiety, close friendship and food security. Assessment of associations was conducted through both bivariate and multivariate logistic regression analyses at 95% confidence interval.

Figure 1. Geographical location of Bolivia.

RESULTS

A total of 3696 students participated in the survey, of which 50.5% were males. Most of the students were either of age 14 years (27.4%) or 15 years (29.2%). About 1 in 3 students (32.8%) missed classes or school without permission. Overall, 31.3% of the students reported being bullied and 34.8% were physically attacked. Significantly, more males (44.4%) than females (21.2%) were involved in physical fights ($p < 0.001$). More females (14.8%) than males (7.3%) reported being lonely ($p < 0.001$). Altogether, 15.4% of the students reported that they smoked cigarettes 30 days prior to the survey, and only 3.5% reported that they smoked marijuana in their lifetime. About half (18.6%) of both males and females consumed alcohol, while 15.1% abused it. Overall, only 32.4% of students indicated that their parents or guardians understood their problems and worries. Significantly, more female (23.5%) than male students (13.2%) ever seriously considered attempting suicide ($p < 0.001$). These results are shown in Table 1.

Table 2 shows factors that were associated with suicidal ideation. All the factors that were considered in the analysis were significantly associated with suicidal ideation in both bivariate and multivariate analysis. Compared to students who were aged 16 years or older, students of age of 14 years (AOR = 0.86, 95% CI [0.85, 0.87]) were less likely to seriously consider attempting suicide; while students of age less than 14 years (AOR = 1.06, 95% CI [1.04, 1.08]) and age 15 years (AOR = 1.18, 95% CI [1.16, 1.20]) were more likely to have suicidal ideation. Male students were 34% (AOR = 0.66, 95% CI [0.65, 0.67]) less likely to have suicidal ideation than female students.

In relation to anxiety and loneliness, students who were worried about something that they could not sleep at night were 37% (AOR = 1.37, 95% CI [1.34, 1.39]) more likely to have suicidal ideation than students who were not anxious. Meanwhile, students who felt lonely were 1.75 (95% CI [1.73, 1.77]) times more likely to have suicidal ideation than students who did not.

Students who did not have close friends were more likely to have suicidal ideation than those who had close friends (AOR = 1.03, 95% CI [1.02, 1.05]). Compared to students who did not miss classes or school without permission, students who were truant were 26% (AOR = 1.26, 95% CI [1.24, 1.27]) more likely to seriously consider attempting suicide.

Been bullied, physically attacked or involvement in a physical fight were significantly associated with suicidal ideation. Students who were bullied were 32% (AOR = 1.32, 95% CI [1.31, 1.33]) more likely to have suicidal ideation compared to students who were not bullied. Compared to students who were not physically attacked, those who were attacked were 1.30 (95% CI [1.29, 1.31]) times more likely to have suicidal ideation. Students who were involved in a physical fight were 99% (AOR = 0.99, 95% CI [0.98, 1.00]) more likely to have suicidal ideation compared to those who were not involved in a physical fight.

Smoking cigarettes (AOR = 1.27, 95% CI [1.26, 1.29]); marijuana (AOR = 1.17, 95% CI [1.15, 1.20]) were significantly associated with suicidal ideation. Students who consumed alcohol were 26% (AOR = 1.26, 95% CI [1.24, 1.27]) more likely to have suicidal ideation compared to students who did not consume alcohol. Meanwhile, students who abused alcohol were 1.10 (95% CI [1.09, 1.12]) times more likely to have suicidal ideation compared to those who did not abuse alcohol.

Students who reported that their parents or guardians understood their problems and worries were 25% (AOR = 0.75, 95% CI [0.75, 0.76]) less likely to seriously consider attempting suicide.

DISCUSSION

In this study all the factors that were considered in the analysis were significantly associated with suicidal ideation in both bi-variate and multi-variate analysis. Although the prevalence of suicidal ideation of 18.2% is lower than the rates reported in similar studies in various parts of the world [10, 18, 19], it is common in Bolivia. The prevalence of suicidal ideation among males was about half that among females (13.2% vs 23.5%). This finding was also observed in similar studies done elsewhere [18]. It is, however, surprising that this is the case, as globally, actual suicide deaths occur more among males than females [10]. One study explained that girls had higher suicide attempt risk than boys and 45% of the risk was explained by socio economic, school, mental difficulties and violence [18]. With regard to age variation in relation to suicidal ideation, the study found that some younger age groups were protective, while others were not when compared to the oldest age group. Students who were less than 14 years of age and those that were 15 years of age were more likely to consider attempting suicide. This finding contradicts the findings in the Peru study which did not find any association between age and suicidal ideation and therefore reported an equal risk of suicidal ideation among different aged adolescents [18, 19]. The study by Muula et al. [10] found that adolescents who were less than 14 years of age were more likely to consider committing suicide. This finding and our finding are different from the findings of Liu et al. [20] where increasing age was correlated with suicidal behaviour. We are, however, unable to offer a plausible explanation as to why students who were 14 years of age (compared to students of ages 16 years or older in the current study) were less likely to have suicidal ideation because in most cases, it is the slightly older adolescents who would think of committing suicide more than the younger ones. Muula et al. [10] in their paper explained that younger children may not have developed problem solving skills and as such they are more likely to consider committing suicide than the older ones.

In the present study, being anxious, lonely, having no close friends, missing classes or school without permission were all associated with suicidal ideation. In addition, being bullied, physically attacked, involved in a physical fight were all significantly associated with suicidal ideation. Students who were bullied were 32% more likely to have suicidal ideation while those who were attacked were 30% more likely to have suicidal ideation. This indicates that adolescent violence is an important factor in the study area in Bolivia. Curtailing violence may result in reduced suicidal ideation. In a similar study among Brazilian adolescents, being involved in a physical fight was associated with a higher rate of suicidal ideation [18]. Similarly, being bullied has been observed as an important risk factor of suicidal ideation in study findings in other countries [10, 18]. This indicates that physical and emotional violence against adolescents is related to suicidal ideation.

The current study revealed a significant association between smoking and suicidal ideation. Similarly, in Benin, cigarette smoking was observed as a risk factor of suicidal ideation (14 = 18). Alcohol consumption and abuse were both associated with suicidal ideation in the current study. This association has also been reported in a similar study in Zambia [10]. Students who consumed alcohol were 26% more likely to have suicidal ideation in the current study. We, therefore, assume that preventing initiation of smoking, alcohol consumption among adolescents in Bolivia may be one of the useful strategies to prevent suicidal ideation and in turn prevent suicide.

We observed that students whose parents or guardians understood their problems and worries were less likely to consider committing suicide. Together with the finding that students who had close friends were less likely to have suicidal ideation, healthy parental and peer relationships should be encouraged for adolescents to have good mental health.

In conclusion, adolescent suicidal ideation is a common experience among adolescents in Bolivia. Creating a supportive environment both in school and at home will help adolescents to express their feelings and this will translate into reducing negative incidents of suicidal thoughts. We propose that preventive measures against suicidal ideation be put in place considering the factors that have been found to be significantly associated with suicidal ideation in this study.

ABSTRACT

Adolescent suicidal behavior is a neglected public health issue especially in middle and low income countries. Informed policy decision-making on suicidal behavior will need reliable information on the factors associated with suicidal ideation, which is one of the determinants of suicidal behaviour. The study aimed to identify factors associated with suicidal ideation among junior high school students in Suriname. Both bivariate and multivariate logistic regression analyses at 95% confidence interval were conducted to assess the association between relevant predictor variables and suicidal ideation within the previous twelve months. A total of 1,674 junior high school students responded to the question on suicidal ideation among other questions in a structured questionnaire from the Global School-based Student Health Survey (GSHS). Overall, 13.6% (9.1% of male and 17.9% of female) students reported having had suicidal ideation in the previous 12 months. The analysis showed that being anxious, lonely, having no close friends, being bullied, physically attacked or involved in a physical fight just like smoking cigarettes, alcohol consumption and abuse were all significantly associated with suicidal ideation.

* Corresponding Author's Email: enjunju@yahoo.com.

Interventions that address issues of violence against students, fighting with peers, initiation of smoking, alcohol consumption and abuse may reduce the risk of suicidal ideation.

Keywords: suicidal ideation, prevalence, correlates, Suriname

INTRODUCTION

Suicide is a global public concern as more than 800,000 people commit it every year and for every suicide there are many more who attempt it [1]. A prior suicide attempt is the single most important risk factor for suicide in the general population [1]. In 2012, suicide was the second leading cause of death among 15-29 year olds worldwide and occurs throughout the life span [1-3]. The Global Burden of Disease Study [4] estimated that suicide contributes to 6% of all deaths among young people aged 10-24 years worldwide. Notably, 75% of global suicides occur in low and middle income countries [1, 2]. Suicide is preventable with timely, evidence based and low cost interventions [1, 5]. Suicidal ideation is both a strong risk factor and a stage in the suicidal process from planning to attempt dying [6, 7]. Although not all suicidal ideation materialize into suicide attempts or suicide, it is the first step on to the path to suicide [8]. A 60% rate of transition has been observed from suicidal ideation to first suicide attempt within the first year of ideation on set [7].

Suicidal ideation often emerges in adolescence and is prevalent in this age group, particularly among females [9]. Across 17 European countries, the lifetime prevalence of ideation among students aged 15-16 years ranged from 15% to 31.5%. Across 49 low and middle income countries, 15.3% of adolescents aged 13-15 years had seriously considered suicide in a year prior to the survey. In neighbouring countries to Suriname, the prevalence of suicidal ideation was 14% in Brazil [10] and 18.4% in Guyana [11]. Given that ideation strongly and prospectively relates to suicide attempts and suicide, identifying potentially modifiable risk factors is essential for preventing these deaths [9]. Several environmental, psychosocial and behavioural factors have been found to be associated with suicidal ideation [9, 10] and include: physical, sexual and emotional abuses [8, 9, 12, 13], family problems, social pressure, economic struggle, racism [12, 13], smoking and alcohol consumption [12]. Correlates for suicidal ideation may vary from subpopulation to subpopulation in a country; among countries and continents and, hence, is important that these correlates are established for specific populations. Suicidal ideation prevalence and its associated factors among junior high school students in Suriname are unknown. Therefore, the objectives of the study were to estimate the prevalence of suicidal ideation and identify factors associated with this phenomenon.

METHODS

Suriname is a small country in South America (see Figure 1). It is a sovereign state on the northeastern Atlantic coast of South America. It is bordered by French Guyana to the east, Guyana to the west and Brazil to the south. At just under 165,000 km², it is the smallest

country in South America with a population of approximately 566,000, most of whom live on the country's north coast, in and around the capital and largest city, Paramaribo. It's defined by vast swaths of tropical rainforest, Dutch colonial architecture and a melting-pot culture. On its Atlantic coast is the capital, Paramaribo, where palm gardens grow near Fort Zeelandia, a 17th -century trading post. Paramaribo is also home to Saint Peter and Paul Basilica, a towering wood cathedral consecrated in 1885.

The Global School-based Health Survey (GSHS) was developed by the World Health Organization (WHO) in collaboration with UNICEF, UNESCO and UNAIDS with technical assistance from Centers for Diseases Control and Prevention, Atlanta, Georgia, United States with the aim of providing data on health and social behaviors among school-going adolescent students. This paper presents results of a secondary analysis of the data obtained from the GSHS conducted in 2009 among the junior high school students in Suriname. The survey measured alcohol use; dietary behaviors; drug use; hygiene; mental health; physical activity; protective factors; sexual behaviors; tobacco use; violence and unintentional injury.

The Suriname GSHS used a two-stage cluster sample design in which in the first stage, schools were selected with probability proportional to enrollment size. In the second stage, classes were randomly selected and all students in selected classes were eligible to participate. The school response rate was 100%, the student response rate was 89% and the overall response rate was 89%.

Students self-reported their responses to each question on a computer-scannable answer sheet. Variables that were used in the analysis included: socio-demographic characteristics, having considered suicide, smoking, loneliness, parental understanding, involvement in a fight, truancy, anxiety, close friendship and food security. Assessments of associations were conducted using both bivariate and multivariate logistic regression analyses at 95% confidence interval.

Figure 1. Map of Suriname and its neighbouring countries.

RESULTS

A total of 1698 students participated in the survey of which 51.0% were males. Most of the students were either of age 16 years or older (38.1%) or 15 years (22.2%). About 1 in 4 students (27%) reported being bullied. Overall, 22.1% of students missed classes or school without permission and 24.7% were physically attacked. Significantly ($p < 0.001$), more males (29.9%) than females (12.6%) were involved in a physical fight and also more males (30.5%) than females (13.9%) reported to have missed classes or school without permission. Altogether, 12.2% of the students reported that they smoked cigarettes 30 days prior to the survey. Overall 38.1% of both males and females consumed alcohol, while 19.1% abused it. Overall, 41.4% of students indicated that their parents or guardians understood their problems and worries. Significantly, more female students (17.9%) than male students (9.1%) ever seriously considered attempting suicide. The overall suicidal ideation prevalence rate was 13.6%. These results are shown in Table 1.

Table 2 shows factors that were associated with suicidal ideation. All the factors that were considered in the analysis were significantly associated with suicidal ideation in both bivariate and multivariate analyses. Compared to students who were aged 16 years or older, students of age less than 14 years (AOR = 0.52, 95% CI [0.47, 0.57]) were less likely to seriously consider attempting suicide while students of age 14 years (AOR = 1.22, 95% CI [1.12, 1.33]) and 15 years (AOR = 1.33, 95% CI [1.23, 1.44]) were more likely to have suicidal ideation. Male students were 40% (AOR = 0.60, 95% CI [0.57, 0.63]) less likely to have suicidal ideation than female students.

In relation to anxiety and loneliness, students who were worried about something that they could not sleep at night were 52% (AOR = 1.52, 95% CI [1.43, 1.62]) more likely to have suicidal ideation than students who were not anxious. Meanwhile, students who felt lonely were 1.27 (95% CI [1.20, 1.35]) times more likely to have suicidal ideation than students who did not.

Students who did not have close friends were more likely to have suicidal ideation than those who had close friends (AOR = 1.16, 95% CI [1.09, 1.22]). Compared to students who did not miss classes or school without permission, students who were truant were 7% (AOR = 0.93, 95% CI [0.88, 0.99]) less likely to seriously consider attempting suicide.

Been bullied, physically attacked or involvement in a physical fight were significantly associated with suicidal ideation. Students who were bullied were 41% (AOR = 1.41, 95% CI [1.34, 1.48]) more likely to have suicidal ideation compared to students who were not bullied. Compared to students who were not physically attacked, those who were attacked were 1.11 (95% CI [1.05, 1.17]) times more likely to have suicidal ideation. Students who were involved in a physical fight were 17% (AOR = 1.17, 95% CI [1.11, 1.24]) more likely to have suicidal ideation compared to those who were not involved in a physical fight.

Smoking cigarettes (AOR = 1.26, 95% CI [1.19, 1.34]) was significantly associated with suicidal ideation; Students who consumed alcohol were 13% (AOR = 1.13, 95% CI [1.07, 1.19]) more likely to have suicidal ideation compared to students who did not consume alcohol. Meanwhile, students who abused alcohol were 1.32 (95% CI [1.24, 1.39]) times more likely to have suicidal ideation compared to those who did not abuse alcohol.

Students who reported that their parents or guardians understood their problems and worries were 22% (AOR = 0.78, 95% CI [0.75, 0.82]) less likely to seriously consider attempting suicide.

DISCUSSION

In the current study all the factors that were considered in the analysis were significantly associated with suicidal ideation. The prevalence of suicidal ideation was 13.6% which is higher than the prevalence of suicidal ideation of 10.7% among Americans of Caribbean

descent but lower than the prevalence of suicidal ideation of 17.1% in Brazil [10]. The prevalence of suicidal ideation among males was about half that among females (9.1% vs 17.9%, respectively). This finding was also observed in similar studies done elsewhere [12]. It is, however, surprising that this is the case, as globally, actual suicide deaths occur more among males than females [8].

With regard to the distribution of suicidal ideation by age, the present study found that there was an association between age and suicidal ideation. Students who were less than 14 years of age were less likely to consider committing suicide. This finding contradicts the finding in Peru which did not find any association between age and suicidal ideation [12]. The study by Muula et al. [8] found that adolescents who were less than 14 years of age were more likely to consider committing suicide. Our finding and the finding by Liu et al. [14] indicate that age is correlated with suicidal ideation. We are, however, unable to offer a plausible explanation as why students who were 14 years of age (compared to older age groups) were less likely to have suicidal ideation because in most cases, it is the slightly older adolescents who would think of committing suicide more than the younger ones. Muula et al. [8] in their paper, however, explained that younger children may not have developed problem solving skills and as such they are more likely to consider committing suicide than the older ones.

In the current study, being anxious, lonely, having no close friends, missing classes or school without permission were all associated with suicidal ideation. Been bullied, physically attacked, involved in a physical fight were also significantly associated with suicidal ideation. Students who were bullied were 41% more likely to have suicidal ideation and those who were anxious were 52% more likely to have suicidal ideation. In similar studies elsewhere being involved in a physical fight and bullying were significantly associated with higher rates of suicidal ideation [8, 11, 12]. These findings indicate that physical and emotional violence against adolescents should be considered in efforts to design interventions to prevent suicide.

The present study revealed a significant association between smoking and suicidal ideation. Similarly, another study also observed cigarette smoking as a risk factor of suicidal ideation [9]. Alcohol consumption and abuse were both associated with suicidal ideation in the current study. This association has also been reported in another study [8]. Students who consumed alcohol were 13% more likely to consider committing suicide than those who did not consume alcohol while those that abused alcohol were 32% more likely to consider committing suicide. Therefore, preventing initiation of smoking and alcohol consumption among adolescents in Suriname may be one of the useful strategies to prevent suicide.

In conclusion, suicidal ideation is a significant public health issue among in-school adolescents in Suriname that requires attention. We propose that the design, implementation and evaluation of preventive measures should incorporate the knowledge of the associated factors obtained in the current study.

ACKNOWLEDGMENTS

The authors wish to express their appreciation and gratitude to the World Health Organization (WHO) and Centres for Disease Control (CDC) for making the data available for analysis.

ABSTRACT

Information on the epidemiology of suicidal ideation is scanty in low and middle income countries. In order to contribute to the body of knowledge on suicidal behaviour, a study was conducted to examine the correlates of suicidal ideation among adolescents attending junior high school in Myanmar. Both bivariate and multivariate logistic regression analyses at 95% confidence interval were conducted to establish associations. A total of 2,803 junior high school students responded to the question on suicidal ideation among other questions in a structured questionnaire from the Global School-based Student Health Survey (GSHS). Overall, 1.1% students reported having had suicidal ideation in the previous 12 months. The analysis showed that having no food security, being anxious, lonely, having no close friends, being bullied, physically attacked or involved in a physical fight, alcohol consumption were all significantly associated with suicidal ideation. The study also found that having parents or guardians who do not understand the adolescent's problems and worries was significantly associated with suicidal ideation. Interventions that address issues of food security, violence against students, fighting with peers, initiation of alcohol consumption and those that encourage supportive roles of parents may reduce the risk of suicidal ideation.

INTRODUCTION

Suicide is a global public concern as more than 800,000 people commit it every year and for every suicide there are many more who attempt it [1]. A prior suicide attempt is the single most important risk factor for suicide in the general population [1]. In 2004, suicide was the fourth leading cause of death among young males and the third among young females aged 15-19 years, worldwide [2]. The Global Burden of Disease Study [3] estimated that suicide contributes to 6% of all deaths among young people aged 10-24 years worldwide. It is, however, worthy noting that over the past 25 years there have been major shifts in causes of mortality and morbidity among young people aged 10-24 years [4]. Notably, 75% of global suicides occur in low and middle income countries which are home to more than 90% of the world's children and youths [5]. Compared to high income countries, relatively little is known about the epidemiology of adolescent suicide and suicide behaviours in low and middle income countries [5].

Studies among adolescents from low and middle income countries seem to show considerable rates of prevalence of suicidal ideation: 17.8% in China, 17.1% in Philippines, and in African countries; 19.6% in Uganda, 23.1% in Botswana, 27.9 % in Kenya and 31.9% in Zambia [6]. Local studies in Thailand found a prevalence of suicidal ideation of 4.0% among high school students [6, 7].

Suicide is preventable with timely and low cost interventions [1]. It is reported that 85.7% of those who make a suicide attempt have seriously thought about doing so earlier. To date, several environmental, psychosocial and behavioral factors have been found to be associated with suicidal ideation, suicidal attempts and suicide in studies conducted in various countries. Physical, sexual and emotional abuses have been associated with adolescent suicidal ideation and attempts [7-9].

Although not all suicidal ideation materialize into suicide attempts or suicide, it is the first step on to the path to suicide [10]. Suicidal ideation is both a strong risk factor and a stage in the suicidal process from planning to attempt dying [11, 12]. A 60% rate of transition had been observed from suicidal ideation to first suicide attempt within the first year of ideation on set [12]. Hence, one of the key challenges for preventing suicide among adolescents is improving the prediction of suicide risk [13]. Given that suicide ideation strongly and prospectively relates to suicide attempts and suicide, identifying potentially modifiable risk factors is essential for preventing these deaths [5]. Many factors associated with youth suicidal behaviours in low and middle income countries overlap with established risk factors from high income countries [5].

In a study conducted in 2008 in Thailand, a neighbouring country to Myanmar, the overall prevalence of suicidal ideation was 8.8%, and factors that were associated with suicidal ideation were sadness, lack of parental attachment and current alcohol use [6]. Studies were conducted between 2003 and 2012 in China [14], another neighbouring country to Myanmar. Meta-analysis of these studies estimated the lifetime prevalence of suicidal ideation as 3.9%. This figure cannot, however, be compared to the prevalence of suicidal

ideation found in Myanmar because the studies in China were conducted in age groups above 15 years.

Suicidal ideation and its associated factors among junior high school students in Myanmar are unknown. Therefore, the objectives of this study were to determine the prevalence of suicidal ideation as well as factors associated with this phenomenon.

METHODS

The study setting for the current study was Myanmar. Myanmar (formerly Burma) is a Southeast Asian nation of more than 100 ethnic groups, bordering India, Bangladesh, China, Laos and Thailand (see Figure 1).

The Global School-based Health Survey (GSHS) was developed by the World Health Organization (WHO) in collaboration with UNICEF, UNESCO and UNAIDS with technical assistance from Centers for Diseases Control and Prevention, Atlanta, Georgia, United States with the aim of providing data on health and social behaviors among school-going adolescent students. This paper presents results of a secondary analysis of the data obtained from the GSHS conducted in 2007 among the junior high school students in Myanmar. The survey measured alcohol use; dietary behaviors; drug use; hygiene; mental health; physical activity; protective factors; sexual behaviors; tobacco use; violence and unintentional injury.

Figure 1. Myanmar and its neighbouring countries.

In the Myanmar GSHS, a two-stage cluster sample design was used. In the first stage, schools were selected with probability proportional to enrollment size. In the second stage, classes were randomly selected and all students in selected classes were eligible to participate. The school response rate was 100% and that for students was 95%, with an overall response rate was 95%.

Variables that were used in the current study included socio-demographic characteristics, having considered suicide, smoking, loneliness, parental understanding,

involvement in a fight, truancy, anxiety, close friendship and food security. Assessments of associations were conducted using both bivariate and multivariate logistic regression analyses at 95% confidence interval.

RESULTS

A total of 2806 students participated in the Myanmar 2007 Global School-based Students Health Survey, of which 49.8% were males. Most of the students were either of age less than 14 years (40.7%) or 14 years (25.2%). About 1 in 4 students (21.8%) missed classes or school without permission. Overall, 20.7% of students reported being bullied and 23.1% were physically attacked. Significantly, more males (21.7%) than females (9.8%) were involved in a physical fight ($p < 0.001$). Altogether, 2.9% of the students reported that they smoked cigarettes 30 days prior to the survey, and none reported that they smoked marijuana in their lifetime. Only 1.4% of both males and females consumed alcohol, while 2.6% abused it. Overall, 60.9% of students indicated that their parents or guardians understood their problems and worries. There was no significant difference ($p = 0.303$) in suicidal ideation rates between female students (1.2%) and male students (1.1%). These results are shown in Table 1.

Table 2 shows factors that were associated with suicidal ideation. All the factors, except gender, that were considered in the analysis were significantly associated with suicidal ideation in bivariate analyses. However, in multi-variate analysis, cigarette smoking, and alcohol abuse were no longer associated with suicidal ideation.

Compared to students who were aged 16 years or older, students of age less than 14 years were 2.71 (95% CI [2.61, 2.81]) times more likely to have suicidal ideation than students who did not. Students who were 14 years (AOR = 0.45, 95% CI [0.43, 0.48]) were less likely to seriously consider attempting suicide; while students aged 15 years (AOR = 0.62, 95% CI [0.59, 0.66]) were less likely to consider attempting suicide. Gender was not significantly associated with suicidal ideation.

In relation to anxiety and loneliness, students who were worried about something such that they could not sleep at night were 2.17 (95% CI [2.10, 2.24]) times more likely to have suicidal ideation than students who were not anxious. Meanwhile, students who felt lonely were 1.82 (95% CI [1.76, 1.88]) times more likely to have suicidal ideation than students who did not.

Students who did not have close friends were more likely to have suicidal ideation than those who had close friends (AOR = 1.14, 95% CI [1.07, 1.21]). Compared to students who did not miss classes or school without permission, students who were truant were 19% (AOR = 1.19, 95% CI [1.16, 1.22]) more likely to seriously consider attempting suicide.

Been bullied and physically attacked were significantly associated with suicidal ideation. Students who were bullied were (AOR = 1.00, 95% CI [1.00, 1.02]) more likely to have suicidal ideation compared to students who were not bullied. Compared to students who were not physically attacked, those who were attacked were 2.38 (95% CI [2.32, 2.44]) times more likely to have suicidal ideation. Students who were involved in a physical fight were 18% (AOR = 0.82, 95% CI [0.80, 0.85]) less likely to have suicidal ideation compared to those who were not in a physical fight.

Students who consumed alcohol were 81% (AOR = 1.81, 95% CI [1.74, 1.89]) more likely to have suicidal ideation compared to students who did not consume alcohol.

Students who reported that their parents or guardians understood their problems and worries were 6% (AOR = 0.94, 95% CI [0.92, 0.96]) less likely to seriously consider attempting suicide.

DISCUSSION

The prevalence of suicidal ideation in the current study was 1.1% which is lower than what has been reported in similar studies in various parts of the world [10, 15]. The low rate of suicidal ideation in Myanmar may be due to Buddhism. About 95% of the population is Buddhist and one of the five actions of Buddhism requires a lay Buddhist to train himself or herself to avoid destroying life [6]. Religious affiliation and practice among Burmese people may play an important role in preventing them from suicidal behaviour when they encounter hopeless feelings in their lives [6]. Some studies have reported strong sociocultural influence especially among middle and high income families in relation to suicide attempt reports [16]. In various studies conducted in China between 2003 and 2011 among the aging populations, there were vast variations in the prevalence of suicidal ideation between various regions. The prevalence ranged from 2.2% to 41.2% [17]. In a meta-analysis study to establish the prevalence of suicidal ideation and suicide attempts in the general population of mainland China in the age range 15 to 18 years, the prevalence of suicidal Ideation ranged from 2.8 to 4.9 % [14].

The prevalence of suicidal ideation was similar in males and females (1.1% vs 1.2%). This finding was also observed in another study elsewhere [15]. It is, however, surprising that this is the case, as globally, actual suicide deaths occur more among males than females [10]. With regard to age variation, the study found that there was an association between age and suicidal ideation which indicates some unequal risk of suicidal ideation among different aged adolescents. Students who were less than 14 years of age were 2.71 times more likely to consider attempting suicide than those who were of age 16 years or older. Meanwhile students who were of age 14 or 15 years were less likely to have suicidal thoughts compared to students of age 16 years or older. This finding contradicts the findings in Peru and Uganda which did not find any association between age and suicidal ideation and therefore reported an equal risk of suicidal ideation among different aged adolescents [15, 18]. The study by Muula et al. [10] found that adolescents who were less than 14 years of age were more likely to consider committing suicide. This finding and our finding are different from the findings of Liu et al. [19] who found increasing age to be correlated with suicidal behaviour. We are, however, unable to offer a plausible explanation as why students who were less than 14 years of age were more likely to have suicidal ideation because in most cases, it is the slightly older adolescents who would think of committing suicide more than the younger ones. Muula et al. [10] in their paper, however, explained that younger children may not have developed problem solving skills and as such they are more likely to consider committing suicide than the older ones.

In the present study, being anxious, lonely, having no close friends, missing classes or school without permission and parental understanding were all associated with suicidal ideation. Being bullied, physically attacked, involved in a physical fight and alcohol use were also significantly associated with suicidal ideation. Students who were attacked were 2.38 times more likely to have suicidal ideation than those who were not and those who were lonely were 82% more likely to have suicidal ideation. In a similar study conducted in 2008, among Thai adolescents, being sad, anxious, lack of parental understanding, alcohol use and use of illicit drugs were associated with a higher rate of suicidal ideation [6]. Similarly, being bullied is an important risk factor of suicidal ideation in study findings in other countries [10,

15]. These results suggest that many factors will have to be considered in designing interventions to curtail suicidal ideation, although the prevalence was low.

ACKNOWLEDGMENTS

The authors wish to express their appreciation and gratitude to the World Health Organization (WHO) and Centres for Disease Control (CDC) for making the data available for analysis.

ABSTRACT

Break the Cycle of Children's Environmental Health Disparities (*Break the Cycle*) is an annual collaborative interdisciplinary research and training program involving university students in academic tracks that focus on the impact of adverse social, economic and environmental factors on children's health and development. The target populations are communities where poverty is associated with social and political marginalization exposing children to environmental hazards with risks to their health and well-being. Each participating student develops a project that focuses on preventing or reducing adverse environmental factors in order to benefit the children who live in these communities by reducing the likelihood of health disparities and improving their health and well-being. At the end of the project period, students present their findings at a national conference and write papers, which are published in this volume. The projects in any given year cover a range of social, economic, environmental and political factors that operate over the lifespan, and have an influence on individual, family, community, and societal elements. Most importantly, they inform us about children's environmental health disparities and propose solutions to reduce and eliminate health disparities and promote health equity for all children. The phrase *Break the Cycle* in this context uses the ecological construct of the cycle of environmental health disparities (Figure 1) and represents a framework for reducing health disparities and promoting health equity among vulnerable children. The student projects are intended to break the cycle and liberate children from the intergenerational cycle of health disparities, so they can grow and develop to their full potential. Through their participation in this academic process, the students gain knowledge, insight and skills to enable them to advance in their careers and become future leaders in children's environmental health research, clinical practice and advocacy. The papers in this publication represent the work of students who participated in the 13th Annual *Break the Cycle* program 2017-2018.

INTRODUCTION

Children who grow up in poverty are often exposed to poor indoor air quality, which increases the risk for asthma and respiratory disorders, and to high lead levels from old paint and plumbing in older houses which can result in adverse health outcomes [1]. In addition, the children are at risk for a variety of other environmental exposures because their poor neighborhoods are more likely to be located near roadways where the air is polluted with exhausts from motor vehicles, or near factories, and even toxic waste sites. Their neighborhoods and schools are often poorly serviced with visible litter, trash and general degradation, not to mention poor lighting at night which increases risks of assault and other

crimes, as well as absence of green spaces for recreation [2]. Furthermore, the emotional toll on the children from multiple stressors, including food insecurity, housing insecurity, and fear of physical injury from neglect and abuse which, cumulatively, can result in the physiological phenomenon of chronically elevated cortisol levels and “toxic stress” [3]. The toxic stress syndrome is associated with adverse structural and functional changes in the brain resulting in life-long consequences that can be associated with a reduction in brain volume in white matter, in grey matter, and specifically in the hippocampus and amygdala with developmental, learning, behavior and other functional consequences [4]. As they reach adolescence, they are more likely to experience school failure and engage in risky behaviors, including substance abuse, gang membership, and crimes which can result in incarceration or death from drugs or gun violence. The chronically elevated cortisol levels associated with toxic stress also affect the cardiovascular, immune and hormonal systems, resulting in an increased likelihood of adverse health outcomes in adulthood including obesity, diabetes, and hypertension, with associated morbidity and mortality [3].

Figure 1. Cycle of environmental health disparities [9].

The risks for children are greater than they are for adults, because children breathe more air, drink more water, and eat more food for their body weight than adults, so their exposure load through polluted air, water and soil is greater [5]. Yet, as vulnerable as the children are, so much more sensitive is the fetus. Therefore, the exposure of a pregnant woman to environmental toxins not only affects her health and well-being but can have serious and permanent effects on her fetus. Despite the physiological protective elements in the placenta, many toxins do enter the fetal circulation and can affect organ system development, anatomically and physiologically. Many substances can cross the blood-brain barrier and adversely affect the developing brain resulting in disorders of development and learning with

risks for learning disabilities, such as ADHD, and Autism [6]. These children also have the misfortune of living in poor neighborhoods and attending older, more dilapidated, schools, with teachers who are also suffering from the stress of adverse environmental factors. The combined effects of environmental stresses and negative educational experiences result in high drop-out rates and low graduation rates [7]. Limited education leads to poor employment opportunities, or work with low pay, trapping the young people in the poorer neighborhoods with the older houses in states of disrepair, contributing to exposures to indoor hazards of lead, mold, and other possible contaminants, as well as emotional stress with depression, anxiety about the future with despair and social isolation [8].

This assault of adverse social, economic and environmental factors results in unfavorable health, developmental, and educational outcomes that compromise the child's opportunity for economic and social success and devolves into the perpetuation of an intergenerational cycle. It is the codification of this ecological construct that embodies the concept of the cycle of children's environmental health disparities (see Figure 1).

BREAK THE CYCLE PROGRAM

"Break the Cycle of Children's Environmental Health Disparities" (*Break the Cycle*) is an annual collaborative interdisciplinary research and training program involving university students in academic tracks that explore the impact of adverse social, economic, and environmental factors on children's health, development, and education. Each student develops a project that focuses on preventing or reducing environment related disorders for children who live in communities where environmental hazards are related to circumstances of social and economic disadvantage. At the conclusion of the project, the students present the results of their projects at a national conference and write papers which are published in a journal supplement devoted to the collection of projects from each given year [9].

Each annual program begins with a call for proposals from students which are then subjected to a competitive review process that evaluates the quality of the proposal, relevance to children's environmental health disparities, creativity, and feasibility. The 10 best proposals are selected to work with their academic mentors and with the *Break the Cycle* faculty to complete their projects. The students and their mentors are required to participate in monthly conference calls, during which the progress of each project is reviewed, additional perspectives are explored, and constructive guidance is provided. During these conference calls, the students and their mentors also have an opportunity to communicate and collaborate with their counterparts at other universities.

Since the inception of the Break the cycle program in 2004-2005, we have had 13 annual programs and worked with over 100 students representing 30 different university departments in 10 states in the United States (US), as well as students from countries in Latin America, Europe, and Africa. To date, we have had 10 monographs published in international journals and 10 books in a public health series. In 2012, we completed a survey of past students who rated their experience with *Break the Cycle* valuable, and many reported that they pursued careers relating to their *Break the Cycle* projects [10].

The program was started with the expectation that the projects would make a positive difference by improving the health and well-being of children, their families, and their

communities. It was also envisioned that the students would be inspired to pursue careers that focused on reducing health disparities and in becoming the leaders of the future. Furthermore, because each student has a mentor in the home university, we anticipated that the faculty mentors would add elements of the concept and literature on the subject into their curricula, and thereby promote further research and academic interest in this field (see box 1).

We also expected that the participating students would inspire peers in their academic, social and professional circles, and that the interdisciplinary nature of the program with participation of students at other universities around the world would be stimulating and inspiring (see box 2). The 2012 survey also showed that students derived significant benefit from all aspects of their participation in the process, which included the practical aspects of conducting a research project, experience in preparing and delivering a presentation and writing a manuscript. Each student gained knowledge about children's environmental health and environmental health disparities as well as being exposed to different perspectives from the other student projects. Many participants reported that their participation in the program influenced their career choice [10].

Box 1. Project guidelines

- University faculty identify students with an interest in this topic area and support the student in the selection of an idea for projects that explore environmental factors that adversely affect the health of children living in circumstances of social and economic disadvantage. Alternatively, students interested in a specific project can initiate the application process and identify mentors to work with them.
- The students submit their proposals which are reviewed by the *Break the Cycle* faculty. The process is competitive with only 10 projects being selected each year.
- During the project period, there are monthly conference calls with all students and mentors to monitor the progress of the projects, share ideas, and assure that the projects are consistent with the spirit of the *Break the Cycle* concept.
- At the end of the project period, the students present the results of their work at a conference.
- The students are then required to write papers on their projects, which are submitted for publication in an international journal as a monograph of the *Break the Cycle* projects. The papers are also published as chapters in a book.
- Funding for travel expenses within the United States and accommodation for the conference is provided for the student and faculty mentor. A modest stipend is provided to the students once they have completed the project and submitted their paper.
- The progress and careers of the participating students are tracked to evaluate the impact of their participation in the *Break the Cycle* program

Box 2. Desired outcomes

- To inspire students from a variety of academic disciplines to explore the relationship between adverse social, economic and environmental factors and the health, development and education of children and to creatively generate strategies to address the challenges
- To collaborate with an interdisciplinary team of academic leaders from variety of different universities and colleges to get a perspective on the broader issues of this topic area
- To encourage faculty at universities who participate in this program to promote academic interest and social awareness in children's environmental health disparities
- To cultivate future leaders among the students

BREAK THE CYCLE 13 PROJECTS

The papers in this publication represent the interdisciplinary array of creative work by students from universities in six states in the US who participated in the 13th Annual *Break the Cycle* program. The papers in this volume cover the lifespan from consideration of prenatal vulnerabilities of the fetus, supporting mothers in breastfeeding their newborn infants and reading to their children, exploration of the impact of maternal adverse childhood experiences on the infant and child development, considerations of diet, sleep, obesity and school engagement, looking at the impact of neighborhoods and natural disasters on the vulnerability of children. The following are brief reviews of the *Break the Cycle* 13 student projects:

Evaluating Fish-Consumption in Pregnancy: An Opportunity for Neurodevelopmental Health Promotion

Ivorie Stanley, MD, MPH from the University of Illinois in Chicago, looked at the question of fish consumption among pregnant women to determine risks of mercury toxicity for the fetus. Although her findings showed that very few of the women she studied in Chicago did consume fish, the question she raised and the discussion she generated were meaningful and thought-provoking. We have been concerned about mercury toxicity in fish since the dramatic episode in the 1950's when the Chisso chemical company in Japan dumped tons of mercury-containing toxic waste into the Minamata Bay in Japan resulting in almost 1,000 deaths and over 2,000 people were poisoned as a result of eating fish contaminated by the mercury in the bay, most significantly children and pregnant women, resulting in severe neurological consequences [11]. This episode sensitized us to the neurotoxic effects of mercury, particularly in children and pregnant women. Although this was a dramatic episode and alerted us to the risks of dumping toxic waste from factories into our rivers and streams, it also alerted us to the dangers of mercury toxicity in humans. Unfortunately, over time, there has been a contamination of many of our lakes, rivers and streams, and, in the US, this is readily recognized in the Great Lakes region where, during the great industrial age in the USA from the late 19th century well into the middle of the 20th century, industries lined the Saint Lawrence waterway and the burning of fossil fuels in industry sent mercury into the atmosphere which then precipitated into the river and lakes, was converted to methyl mercury by microorganisms and consumed by fish. As a result, today, most waterways and fish contain mercury. Different fish contain different levels of mercury, with the predators having the highest bioaccumulation. Consumption of contaminated fish, therefore, puts vulnerable populations at risk for mercury toxicity. The interesting challenge in this situation is that fish is a healthy food containing omega-3 fatty acids, that have been shown to be a positive factor in brain development. Furthermore, many populations, particularly those who live on the coast or on islands, are almost exclusively dependent on fish for nutrition especially for their protein [12]. This dilemma is addressed by having fish advisories generated by the EPA and other advisory and governmental bodies, that recommend which fish are safe for children and pregnant women and specify the quantities that are safe. Dr. Stanley may not have found what she was looking for in her study, but she certainly presents a thoughtful consideration of fish

consumption among different populations, socioeconomic as well as ethnic, and how to balance the concern about mercury with the importance of good nutrition.

Risk of Preeclampsia in Teen and Inexperienced Mothers in East and Central Harlem

Alexandrah Gichingiri, BS, from the Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai in New York, studied a group of pregnant teenagers at Little Sisters of the Assumption Family Health Service Maternal Outreach Program, a local charitable organization situated in East Harlem where the poverty rate is almost 50%. Although she was specifically looking at the clinical condition of preeclampsia in this population, she opened the discussion on the prevalence and demographics of teen pregnancies and the health consequences for the young women and their offspring [14]. Although teen pregnancies in the US are on the decline, the rate remains substantially higher than in other countries in the western world with significant disparities in the rates for different ethnic and racial groups, by socioeconomic status, and by state. Social determinants of teen pregnancies include poverty, low educational achievement, degraded neighborhoods with racial segregation, and dependence on welfare, especially children in foster care. Rates are also a third higher in rural versus urban populations and 4 times higher in some southern states compared to the northeastern states. One of the most powerful determinants of teen pregnancies is the cumulative effects of Adverse Childhood Experiences (ACE's), with more than 50% of young women with ACE's scores of 8 becoming pregnant as teenagers [15]. There is also a disproportionate level of health problems among pregnant teens which compounds their existing health risks, including nutritional disorders such as obesity, and cardiovascular disorders such as hypertension, which, in turn, is associated with preeclampsia. Furthermore, there are increased rates of adverse pregnancy outcomes with increased risks for premature and low birth weight infants with a higher infant mortality rate [14]. One of the more disturbing statistics of pregnancy outcomes (not necessarily for teens only) is maternal mortality in the US, which is more than double what it is in most of the western world, and the disparity within the US of a greater than 3 times pregnancy related death rate for black women compared to white women [16].

The resulting challenge is to improve the education of girls and young women, well before they are likely to become pregnant, and provide healthcare to all, with a special attention during pregnancy because of the risks to mother and baby.

Barriers and Promoters to Initiating and Sustaining Breastfeeding among African American Women

Danielle Dimacali, BS, from the Emory University Nell Hodgson Woodruff School of Nursing in Atlanta, Georgia explored the positive factors that were associated with breastfeeding among a group of African American mothers. Breastfeeding is the identifying characteristic of all mammals; after all, the term mammal was derived from the Latin word *mamma* which means breast [17]. Breast feeding is a critical part of the human condition.

This biological imperative is clearly associated with a positive outcome for the mother, the baby, the family, the community, and the species [18]. In premodern communities where the mother may not have had sufficient milk or was absent for reasons of tribal necessity or had died, another woman would have substituted as a 'wet nurse,' providing the necessary nutrients through surrogate breast feeding. From about 10,000 years ago, humans began domesticating and herding animals rather than hunting and gathering, and, in so doing, had access to animals with a ready supply of milk. So, if human mothers were not able to feed their babies for one reason or another, they could resort to milk from their domesticated animals, such as cows, sheep, goats, donkeys or even camels. They would probably have done this directly at first, before developing appropriately configured drinking vessels for their babies. The value of milk in infant nutrition could not have been missed by our ancestors in seeing the potentially fatal consequences of lack of milk. The word *Kwashiorkor* refers to infants and children who have protein deficiency malnutrition with characteristic physical appearances of swelling of limbs with edema, abdominal distention with skin, hair and teeth changes [19]. The origin of the word comes allegedly from Ghana in Africa and refers to the effects of the birth of a second child, when the mother stops breastfeeding the first child, often in the 2nd year of life. The first child may then be fed adequate calories from the staple starch of the area, but no protein from the milk. As a result of the lack of protein in the diet metabolism is disordered and many organ systems suffer, resulting in a characteristic appearance with loss of pigment in the skin and hair giving them a reddish coloration rather than the usual highly pigmented skin color of African people, with thin limbs and a protuberant abdomen and a sad countenance. If not corrected, this can lead to death, most commonly from susceptibility to an infection such as gastroenteritis (often from drinking contaminated water) or even measles (the children are often inadequately immunized).

Some form of dehydrated or partially dehydrated milk products have been present in past civilizations, but, after the industrial revolution, large scale production of dried milk was a positive development in assuring adequate infant nutrition and saving lives especially in difficult times, because it lasts longer than regular milk, could be transported great distances, and could be readily reconstituted with clean water. One of the major problems in developing countries, particularly in Africa, is the limited availability of clean water, resulting in reconstitution of the milk formula with contaminated water, introducing pathological bacteria which results in gastroenteritis and can be fatal, especially in undernourished children (see above). Another problem with reconstituted powdered milk is that it is costly, especially to poor mothers. In order to save they may put less powder and more water, to make the supply last longer, and, in so doing, reduce the protein intake for the children, which can also result in malnutrition.

With the development of powdered infant formulas and industrial production and marketing, the nutritional value of milk became more readily available and accessible, which improved infant nutrition in poor areas of the world but, in the process, resulted in the reduction in the prevalence of breast feeding. In the mid-20th Century, formula feeding was favored across socioeconomic boundaries [18]. However, as we came to appreciate the benefits of breastfeeding and the potentially negative health outcomes of exclusive formula feeding, there has been an increasing trend to breastfeeding. While the trend to breastfeeding has been positive, it has not been uniformly adopted in US society. For a variety of factors, low income minority women are less likely to breast feed [20]. In her exploration of the barriers to breastfeeding, Danielle Dimacali, examines the characteristics of African

American women who have successfully breastfed their infants, giving her insights into strategies that can help to encourage breastfeeding among groups of African American women who are less likely to breast feed, and improve the health and wellbeing of their offspring.

Maternal Childhood Adversity and Early Parenting: Implications for Infant Neurodevelopment

April L. Brown, MA, MPH, in the Department of Psychology at Emory University in Atlanta, Georgia explored the concept of the Cycle of Environmental Health Disparities in the context of children who grow up in poverty or in marginalized communities, and who are also more likely to be exposed to environmental hazards, and experience cumulative and prolonged stresses which can have long term impacts on their health, development, learning, behavior and general well-being. The recognition of this phenomenon has been codified in the concept of Adverse Childhood Experiences (ACEs) and is a major focus of public health efforts of the Centers for Disease Control and Prevention (CDC) [21]. The ACEs have a scoring system that is measured by the number of adverse experiences, on a scale from 1-10 (where 1 is the lowest score and 10 is the highest). The higher the score, the more predictive the adverse long-term outcome. Measured long term outcomes have revealed increases in health-related problems, such as diabetes and hypertension, learning disabilities and difficulties with focus and attention, behavior disorders with increased risks of substance abuse, violence and early death. As was stated in the paper on preeclampsia among teenagers in this volume, the greater the ACEs score, the more likely is a young teenager to become pregnant – with the likelihood increasing with increasing scores [15]. So, too, is there a likelihood that the greater the ACEs score, the greater the likelihood of consequences, but it should also be noted that even the lowest score in vulnerable children can have significant consequences [22], while even for relatively high scores, the phenomenon of resilience can result in a positive outcome particularly associated with high levels of social support and working with the parents [23, 24]. It is therefore, critical to identify the children early and provide appropriate interventions to assure a positive impact of growth and development. The CDC also promotes strategies to prevent ACEs and their effects (see Figure 2).

Figure 2. From the CDC about adverse childhood experiences [21].

In her project looking at the impact of maternal ACEs scores on the children, April Brown is in the early stage of her research and has just scratched the surface by looking at very young infants. In other studies on children of mothers who have high ACEs scores, the findings do reflect a correlation between maternal ACEs and children's development and behavior, as well as correlation the ACE score and likelihood of adverse outcome [25].

Young Minds, Young Readers: Dialogic Reading with Adolescent Mothers and Their Children

Diana Abarca, BS, University of Central Florida, Orlando, FL, focused on adolescent mothers who are living in poverty, dropping out of high school, unemployed, and at risk for mental health issues, which may compromise their parenting skills and leave them trapped with their children in the cycle of environmental health disparities. Her project looked at how to break the cycle by teaching the young mothers to read to their young children, expecting that the mothers would be empowered to learn and build their own self esteem at the same time as they encouraged their children to become familiar with books, with reading and with learning. This is expected to help with their language acquisition and increase the likelihood of academic success, which in turn, leads to improved employment opportunities and higher income when they grow up, thus breaking the intergenerational cycle of health disparities.

Unfortunately, as the timing of her project was short and with the challenge of recruitment, she was only able to work with 1 mother who had twin boys. Although she was not able to demonstrate an objective benefit with the two boys in such a short time, she was able to demonstrate that the young mother was able to learn how to read to her children.

There is, ample evidence that exposure of young children to books and reading has a positive impact on their language development and learning, with the promise of a brighter future for them academically by improving school readiness. One program that addresses this need among vulnerable children is called Reach Out and Read, which offers books to children from low income families and encourages reading in these young families [26, 27]. Reach Out and Read was started almost 30 years ago and has grown from its original site at the Boston Medical Center to thousands of sites around the US, reaching millions of children [28].

Another program initiated at the University of Chicago is the Thirty Million Words initiative, which encourages early use of language from birth by talking and singing to the infant [29]. In a recent Monthly Feature in the AAP journal *Pediatrics*, the title of which, *Talk, Read, Sing: Early Language Exposure As an Overlooked Social Determinant of Health* clearly links early exposure to language and language acquisition to developmental, academic and social success in life [30].

There is no question that improving a child's ability to read and encouraging a spirit of learning is the beginning of a promising academic experience in school, and with the improved education, improved opportunities for employment and a stable and secure income. This also promotes resilience in the children should they experience adverse events and stresses in their lives. Thus, early exposure to language and reading, can reverse the effects of poverty and other adverse childhood experiences and break the cycle of children's environmental health disparities.

Breaking the Cycle: Changing Sleep Habits to Decrease Obesity

Kristina Caffey, a student at the College of Nursing, University of South Alabama, in Mobile, Alabama, evaluated the sleep characteristics of children from a low-income urban area and the barriers these children have in developing healthy sleep behaviors. She worked with a team of mentors from the Nursing School and the School of Psychology to look at the relationship between sleep habits, nutrition and learning. What she found was that the ecological set of environmental factors, barriers and habits factors associated with poverty contributed to the adverse health outcomes. The adverse health outcomes she studied were those of obesity with its associated health impacts, school performance, which is impacted by the adverse personal experiences associated with poverty, the environmental factors associated with the built environment of the neighborhood, and the structural and educational realities of schools in the poor neighborhoods. All these factors contribute substantially and cumulatively to the cycle of environmental health disparities among children who grow up and live under these circumstances.

In this project, she connected with families through questionnaires and focus groups, obtaining information directly from the families primarily about sleep practices for their children. What she found were not unexpected barriers to sleep, i.e., electronic use by the children before bed, co-sleeping, and waking at night for a drink or snack, all of which resulted in reduced quantity and quality of sleep that affected daytime behavior, learning and physiological well-being. The environmental realities of poor households with limited space, often malfunctioning indoor climate control, ambient noise and, more often than not, parental stress leading to insecurity, all affect sleep patterns and result in the adverse developmental, behavioral, learning and health outcomes.

She also demonstrated that involvement with the families, in identifying potentially modifiable environmental and behavioral elements, could break the cycle and alter the negative trajectory into a more positive and healthier lifestyle. The lessons from this study include the importance of getting to know the families, learning about their specific patterns of behavior, around sleep in this case, and helping to guide and direct changes in behavior and practices that foster healthier patterns of behavior with consequent improvements in quality of life, health and function.

Study of Childhood Obesity in Neighborhoods Undergoing Gentrification

Brennan Rhodes-Bratton from Columbia University, Mailman School of Public Health, Department of Sociomedical Sciences in New York City, looked at the impacts of gentrification of poor neighborhoods on children's health, with a focus on nutrition and obesity. This topic is especially vexing because, in the historical context of urban living in the US, cities once thrived, but then with increases in wealth in the population and the explosion in automobile use, the more affluent and mobile populations moved to open spaces in suburbs. As the wealthier families moved into the suburbs, the poorer citizens moved into the cities. In the last decade of the 20th Century, large cities in the US were predominantly populated by poor people of color, with degraded and dilapidated housing and neighborhoods. In fact, the combination of poor maintenance of city infrastructure, with the low tax base that

could not provide enough resources to make a positive difference, resulted in the dramatic picture of urban blight. Poor schools provided poor education, with high rates of school failure, high drop-out rates, high unemployment, high rate of teenage pregnancies, and a dystopian picture with high rates of drug abuse and crime. With the changing social, economic, cultural and demographic forces that emerged in the late 20th and early 21st Centuries, urban renewal and revitalization became an emerging and expanding pattern across the country. With businesses and more highly paid workers moving back into the cities, buildings were renovated, neighborhoods were rehabilitated, and the tax base was increased to fuel the process of urban growth and development. As the picture began to look good for the cities, the new or returning residents, and for city governments, the plight of the low-income, low-resource, indigenous residents came under stress. If the residents could financially and culturally remain in the areas, they could see some benefits to the health and well-being of children from the neighborhoods in the process of gentrification [31]. However, for many, if not most, the financial and cultural stress would be too great, and, not only would they not benefit from the new riches, but they would suffer the loss of familiarity, of home, of community and of culture. As a result, they would have to move to other neighborhoods outside of the city, find affordable housing and maybe a new job, new schools for their children, new friends, and, try to rebuild a community. These stresses to families can result in adverse health outcomes particularly affecting mental health, and, in consequence, physical health as well [32].

In her project, Rhodes-Bratton chose to look at food and food options for families in the changing neighborhoods. Although there were more and healthier food options in the form of high-end supermarkets and restaurants, these were financially out of reach for the average poor resident of the neighborhood. At the same time, the familiar stores and foods were dwindling, leaving the heads of families with less affordable food options for their children. What she found was that, where a number of fast food options remained, there was no change in the children's BMI, however, in the areas where there was an increase in the number of healthy food options, the children had a significant decrease in BMI scores.

The conclusion of this study is that, while gentrification is good for cities, businesses and the people who work in them, and for a limited number of children of long-term residents, it is disruptive and stressful for the low-income, long-time residents of the areas, particularly those who become displaced. The importance of this realization is that there needs to be more planning in the process with mental health and community support services for the families who are displaced, and assistance with integration into their new neighborhoods and communities [32].

Relationship between Community Characteristics and School Engagement among U.S. Children, National Survey of Children's Health, 2011–2012

Breyanna M. Mikel, in the Department of Epidemiology, School of Public Health at Georgia State University in Atlanta, Georgia, explored the relationship between the built environment and the social and cultural context of neighborhoods and communities, with the concept of school engagement among children K-12. In this project, the usual characteristics of a poor neighborhood are presented as determinants of school engagement and school

performance among the children. The results demonstrate that there is indeed a correlation between the child's social, cultural and physical environment, and school performance. What also emerges is how small differences can have great impacts, which provides further proof of resilience, and the importance of identifying resilience and resilient factors in a child's life. Indeed, she reports that "children living in communities with at least one amenity in their neighborhood (i.e., recreation or community center, library, sidewalks) were more likely to have higher levels of school engagement."

We know that children who live in poor neighborhoods and go to poor schools tend to have more learning disabilities, experience school repetition and school failure, tend to drop out before graduation, and are less likely to be employed [33]. We know that graduation from high school is associated with a greater likelihood of going to college and of finding better jobs with a higher earning potential, enabling the individuals to live in better neighborhoods with better schools which provides better educational opportunities for their children. In this context, school engagement becomes an imperative for children, not only for the sake of school performance in the present, but for the cultivation of long-term intergenerational impacts in securing a future for the next generation, thus breaking the cycle of poverty through enhanced academic achievement.

This project makes the case for societal investment in education and, significantly for this vulnerable population, in schools in communities and in neighborhoods. For poor and vulnerable populations in the US, schools also provide a safety net in providing good nutrition for the children who suffer from food insecurity, counselling for the children who are having emotional difficulties at home, nursing services, and, in some situations, therapies and pediatric care for children with special health care needs, and for children who have learning and other related functional difficulties, there is speech therapy, physical therapy and occupational therapy. As James Heckman, the Nobel Laureate in Economics commented in his long term assessment of the benefits of early intervention for low income vulnerable preschool children in the Perry Preschool Project, "Our estimates of the overall rate of return hover in the range of 7% to 10%, and they are statistically significantly different from zero in most cases." That rate is quite substantial and better than can be realized in many other investments [34].

Schools also provide a forum for community engagement, as was demonstrated by another of our Break the Cycle students during the financial depression beginning around 2009, when families were suffering. The schools not only provided a place to feel welcome, but also to receive food and community support for families [35].

Invisible Threats: Legal Methods to Confront Airborne Hazards in the Home

Prathyusha Chenji, now at Emory University School of Law, did this project while she was at Georgia State University School of Law in Atlanta, Georgia. She looked at the impact of poor housing conditions on the health of children, with a focus on asthma. Recognizing that low income populations are more likely to live in older homes where there was a greater likelihood of asthma triggers which can aggravate asthma in children, she sought to develop guidelines for the families to advocate on behalf of their children. She also recognized that there might be hesitation on the part of families to challenge their landlords fearing retaliation

and possible eviction. In order to help the families secure the necessary modifications and remediations to their rental homes, she developed a ‘worksheet’ for parents to use as a guide to assess the presence of asthma triggers in the home. She also provided the families with information on their legal rights as renters, and offered recommendations for them on how to go about securing legal aid, if necessary, in order to make their case with the landlord. The relationship between poor housing conditions and children’s health has been a focus of Federal agencies like HUD (Housing and Urban Development) which developed the Healthy Homes Initiative in 1999 to protect children and their families from housing-related health and safety hazards [36]. A previous Break the Cycle student had looked at this initiative in relation to asthma reinforcing the importance of the comprehensive approach to addressing children’s asthma by developing a comprehensive approach to dealing with asthma triggers in the home [37].

Children’s Health and Safety Risks Posed by Irrigation Water in Northern Utah

Kristen R. Koci, BS, in the Department of Sociology, Social Work, and Anthropology, Utah State University, Logan, Utah looked at a unique situation to Northern Utah, where irrigation water runs through city streets and is used for residential purposes. She noted the potential risk to children’s health and safety, both in terms of the risks for drowning of young children as well as the risks of the possible chemical or bacterial contaminants from runoffs, with children in lower socioeconomic communities experiencing more exposure pathways and greater levels of vulnerability. Her project involved a survey of two groups of stakeholders, one of which were the families who had grown up with the irrigations ditches and had fond memories of playing in the ditches from their childhood, took it as a fact of life, and were not concerned in the least; the other group was represented by the scientific research community who expressed concern about the risks. What emerged, apart from the interesting dichotomy of response was that there was no data on the water quality and, without objective data, each group can claim that they are correct.

In general, water quality of runoff, which contributes to the water in the irrigation channels, is different in urban, suburban, and rural areas. In urban areas, the runoff is potentially more complex and toxic, depending on local industries. It can contain chemical compounds as well as coliform bacteria. In the rural areas, the contaminants are mainly from the pesticides and herbicides from agricultural applications. In suburban areas, the runoff can also include pesticides and herbicides from garden applications [38]. Thus, an assessment of water quality is a very important step in determining the relative safety or risk for children playing in those irrigation ditches.

Environmental Justice for Vulnerable Florida Children in Hurricane Aftermath

Manmit Singh, BS and Dylan Avery, from the Nell Hodgson Woodruff School of Nursing, at Emory University, in Atlanta, Georgia, performed a literature review to identify

environmental and socioeconomic factors that affect vulnerability and resilience of communities in the event of a hurricane, particularly in selected parts of South Florida. They found that, while environmental vulnerability is a reality in the entire state of Florida, socioeconomic vulnerability varies widely throughout the state. Interestingly, they found that the counties in Florida that are highly vulnerable according to the Social Vulnerability Index (SVI) were the inland counties with the greatest proportional population of children under the age of 18 years old. The realities of vulnerability to natural disasters is that the low resource communities are more vulnerable because of location. Furthermore, the families are less likely to have insurance or other resources to recoup their losses and may find themselves homeless. Images of Hurricane Katrina of 2005 showed how the poor African American families found themselves forced to take refuge in the Superdome for lack of other feasible alternatives. After the destruction of their property, many had to leave the state to find work and live elsewhere [39].

As the impact of climate changes result in increases in natural disasters like hurricanes, floods, snowstorms, droughts, wildfires, and other extreme weather phenomena, we are going to see the impact on society, the economy and the most vulnerable populations especially the children [40].

Social Media as a Tool for Breaking the Cycle of Children's Environmental Health Disparities

Talia Bernhard from the College of Arts and Sciences and Faith Bygrave from the Nell Hodgson School of Nursing, at Emory University in Atlanta, Georgia, raised our awareness of the current phenomenon of Social Media by presenting a case for the potential value of social media in promoting children's health and children's environmental health, to help to Break the Cycle of children's environmental health disparities. There is no question that social media, in all the diverse and often consuming forms, has been a force in our society for the good and for the not so good. Like all forces that we encounter, the question becomes how we harness it for positive effect on the health and well-being of our society, and how we control the negative and potentially destructive power that it has and can unleash.

These two students surveyed children's environmental health professionals, asking about social media habits, measures of success, challenges, and communication strategies. From the health disparities perspective, they asked about whether the respondents focused their efforts on vulnerable populations. Although many used a range of social media, a minority focused on vulnerable populations, and only a few exclusively. As this is a new and emerging field of endeavor with a significant potential impact, we are still in the early stages in our understanding and application of social media in promoting children's health, children's environmental health and children's environmental health disparities.

In a review of literature on social media interventions and promotion of health equity, a group in Canada found that social media interventions were effective in certain populations at risk for disadvantage, including youth, older adults, low socioeconomic populations and in rural communities [41]. They then created a list of highlights based on their findings:

- The use of social media interventions has been increasing in the field of public health as they can cross geographical and physical access barriers.
- Eleven systematic reviews found mixed effects of social media interventions on improving health outcomes and healthy behaviors.
- Some of the reviewed studies found benefits from social media interventions while others found no change or found that outcomes were worse than those from non-social media interventions.
- We know little about how the design and implementation features and the intensity and duration of interventions could improve health or whether they could increase negative behaviors, stigmatization, or exacerbation of health inequities.
- Many of the studies used social media platforms that were developed by the researchers. The effects of using existing social networks with commercial platforms, such as Facebook and Twitter, as part of social media health interventions are unknown.

This paper was published in 2016 using data from previous studies therefore was not quite up to date for 2019, but the gist is clear: there is value in harnessing social media for improving health communication. Because social media can reach vulnerable populations, it can serve to Break the Cycle of children's health disparities and promote greater health equity. This student project contributes to the accumulating experience with current active social media platforms and how they can be adapted for use in health education and health promotion especially for vulnerable population. We appreciate the glimpse that the two students have provided into harnessing the power of this new technology and its potential application to promoting the health and well-being of all children. However, we need to be highly sensitive and cognizant of the potential negative use and impact of social media and factor this awareness into all strategies to use social media on the public.

CONCLUSION

This publication of student projects from our 13th Annual *Break the Cycle* program reflects the diversity of perspectives on the expressions of environmental health disparities in our society and provides strategies that break the cycle. It is gratifying to see that the efforts of each student make a positive difference in our understanding of the health and well-being of children most impacted by adverse social, economic, and environmental factors.

In this collection, we recognize some familiar themes, such as adverse childhood experiences, and the impact of home, school and neighborhood, as well as other social, economic and environmental factors on the health and development and development of children. This year, however, we were brought into the common elements of our time, social media and the impact of climate change. If we are to ensure a safe and secure future for all children, we need to be cognizant of the factors that can affect their health, in all settings at all times. The social media opportunities and options need to be harnessed to positive use in health promotion. We need to harness technology to try to avert the escalation of natural disasters in light of climate change, by reducing greenhouse gases and by utilizing conservation and sustainability practices. In the process of helping our most vulnerable

citizens, we will be helping the entire population and secure a more promising future for generations to come. To this end, we are dedicating our next *Break the Cycle* symposium to exploring the impact of climate change and the rising prevalence and intensity of natural disasters on vulnerable populations.

Chapter 54

BREAK THE CYCLE OF ENVIRONMENTAL DEGRADATION

I. Leslie Rubin^{*}, MD

Department of Pediatrics, Morehouse School of Medicine,
Southeast Pediatric Environmental Health Specialty Unit, Emory University,
Break the Cycle of Health Disparities, Inc and Developmental Pediatrics Specialists,
Atlanta, Georgia, USA

ABSTRACT

Humans have unique abilities among all other living creatures. They have the ability to move about in many different ways and in many different terrains. They have the power of making choices. They have the ability to think ahead and plan ahead. They have the ability to make use of objects in their environment to assist them in their quests. Collectively they have the ability and power to dominate and modify their environment and other living creatures in the environment in order to advance their causes. They have the ability and power to harness natural resources and energy and interact collectively to change the world they live in. They are able to see and assess the consequences of their actions and take action to make necessary changes on what they have found or have done. This collection of characteristics makes them powerful, formidable and dangerous. In the context of this exploration we will marvel at their achievements, celebrate their undeniably exceptional advances, and examine the destructive environmental consequences of their actions, some unanticipated and some ignored. In this commentary, we will look at a local microcosm that illustrates the consequences of environmental neglect and abuse and its inevitable impact on human health, and the subsequent realization and revitalization by collective community action. We will cover a brief history of human habitation on the planet and the associated environmental degradation, accompanied by what has been done to address the process, and recommend a constructive approach to breaking the cycle of environmental degradation toward the promise of a positive future for our planet in good ecological balance with health and well-being for generations to come.

INTRODUCTION

This commentary was inspired by a symposium entitled ‘Envisioning community-based solutions to environmental health disparities’ held during the 13th Annual Break the Cycle of Children’s Environmental Health Disparities Conference in Atlanta, Georgia, in April 2018. The symposium focused on a waterway in northwest Atlanta called Proctor Creek. The Proctor Creek area was once a pristine site with clean, clear water, rich with natural flora and fauna. The creek had once been the source of food, recreation, and pride for the local community but, over time, through economic, social, cultural and political neglect, the community became impoverished, houses and neighborhoods fell into disrepair, and the creek became polluted with sewage runoff, bacteria, chemicals and debris to the extent that it was no longer a source of pride, but of shame.

After many years of tireless grass-roots, collective community effort and advocacy, positive change eventually came from many different social, economic and political trajectories. Urban flight reversed and was replaced by urban renewal, awareness of the impact of the natural and built environment grew, and collaboration among local residents, citizen’s advocacy groups, university schools of public health, the business community and political representatives proliferated. These collective forces came together to clean up the area and restore it to its former source of pleasure and pride [1]. Although this scenario is local to the Atlanta area, it is representative of similar scenarios and patterns that currently play out in many cities and towns in the United States (US) and around the world and provides a lesson on how to break the cycle of environmental degradation.

This paper will attempt to briefly review our human history of settlement on this planet, with our tendency for exploitation and abuse of our environment, and examine critical events in our recent past that have been transformative in breaking the cycle of environmental degradation to reclaim a clean and healthy environment for ourselves, for future generations and for the ecological balance of our planet.

PROCTOR CREEK

Proctor Creek is a waterway that is fed by many minor tributaries before it enters the Chattahoochee River, which then feeds into the Apalachicola River, a relatively short river formed by the confluence of the Chattahoochee and Flint rivers and flows from Florida into Apalachicola Bay in the Gulf of Mexico. The modern settlement of the Proctor Creek area was comprised predominantly of African American families in the early part of the 20th Century on the west side of the growing and bustling city of Atlanta. By mid-Century, the west side of Atlanta had evolved into a culturally rich African American community, home to the largest complex of historically black colleges and universities in the Southeast US. This area was also a major focal point in the Civil Rights Movement of the 1950s and 1960s with a lengthy list of important leaders who have called the watershed home, including WEB Dubois, Dr Martin Luther King, Jr, Maynard Jackson, and Julian Bond [2].

With the dramatic growth of the city of Atlanta in the last quarter of the 20th Century, associated with changing economics and demographics, infrastructural challenges in dealing with sources of water and sewage disposal had to keep pace with the growth. As has been the

case with so many human settlements, the use of natural waterways have been co-opted to serve the interests of the settlements, not only as a source of water for personal and collective consumption, but also for the disposal of wastes and, in the case of larger waterways, the transportation of goods. Proctor Creek, being a relatively small waterway, was not suited to transportation of cargo but was used in the disposal of sewage and other debris of human settlement. As the city of Atlanta grew, notably from the late 1970s, and more dramatically after the Olympic Games in the mid-1990s, so did the amount of waste that was channeled into the Creek, resulting in increasing pollution including human waste, particularly enterocolic pathogens. Although sewage treatment plants were developed, they had limited capacity, with the consequence that major storms often created overflow from the sewage systems into the combined drainage systems, and the contamination of the Creek continued and accumulated [3].

Over time, with ongoing changes in demographics associated with political, economic and environmental forces, Proctor Creek neighborhoods experienced advancing impoverishment. Progressive contamination of the waterways caused by neglect and abuse of the area, with increased illegal dumping of refuse into the waters of the Creek and its tributaries, worsened the environmental degradation. The accumulation of trash coupled with the bacterial contamination and pollution of the water contributed to the degradation of the neighborhoods and their communities. People who could leave did, while those who remained experienced increasing poverty with limited resources. As happens in many poor and unpoliced neighborhoods, the houses fell into disrepair to the point of becoming uninhabitable, with the void filled by the socially destructive combination of drugs, prostitution and crime. As a consequence, not only was the land and water polluted, but the built environment and the culture became a toxic mix of dystopian elements. Proctor Creek neighborhoods and communities became unhealthy and unsafe. Not only were the dwelling structures in disrepair, but the tax base was depleted, leading inevitably to the compromise of the institutions that support the growth and development of children such as schools and other cultural community centers. The resultant effect on the children was a critical undermining of their opportunities to learn, which compromised their opportunities for gainful employment in the future.

By 2010, the population in the area around Proctor Creek was greater than 13,000, over 80% of whom were African American. A Health Impact Assessment for County performed by the Region 4 of the US Environmental Protection Agency (EPA) revealed that the most common emergency room visits for adults were for mental and behavior disorders, asthma and assault, with the most common causes of death being hypertension, mental and behavior disorders and human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS). For children, emergency room visits were most often for unintentional injury [3].

As happens with low income, minority and often disenfranchised communities, there is limited social and political capital, so desires and attempts by the local communities to make changes and improve the situation through an appeal to local municipalities and government often go unheeded and even unanswered. As a result, not only is the situation perpetuated, but aggravated, resulting a spiral of physical degradation along with social and emotional despondence and despair, that perpetuates the cycle of environmental health disparities across generations [4].

Fortunately, human beings are endowed with innate qualities of resilience and determination to survive and to care for their young [5]. For Proctor Creek communities, this was manifest in local citizens coming together to advocate for positive change, for a cleaner and healthier living space. Over the course of years, advocacy groups grew in number, size and influence, and connected with universities and businesses to make significant progress in reaching relevant organizations and members of the Atlanta business community as well as local political representatives [1]. This collective action has resulted in a process of revitalization of the Proctor Creek watershed, along with other major gentrification projects in inner city Atlanta such as the Atlantic Station, an upscale business, residential and social complex, the largest urban Brownfield redevelopment program of that time, which was built on an abandoned factory, foundry and steel mill [6]; and, more recently, the Atlanta Beltline Project, a residential, business and recreational project, which was developed on an abandoned railroad track [7]. Both of these revitalization projects have been instrumental in bringing city residents of all ethnicities and socioeconomic strata together in common cause, and represent vibrant examples of breaking the cycle of environmental degradation in a local area, with lessons for tackling much of what remains to be done to restore a safe and healthy environment with benefits to all.

Figure 1. Ecosystems services – conceptual framework for a healthy and supportive environment [8].

The US Environmental Protection Agency (EPA) considers a healthy environment in the context of an overarching principle of Ecosystems Services, which refers to those benefits to health and well-being that humans receive from nature, including our food and water, security, and economy [8]. It requires that we remain conscious and aware of the links between our surrounding environment and our well-being when we are engaged in making decisions about develop community infrastructure or managing the land surrounding our communities (see figure 1).

HUMAN PRESENCE ON THE PLANET

Human beings, known as *Homo Sapiens*, the genus of animals with knowledge and wisdom, emerged onto the planet tens of thousands of years ago. While the exact date is not clear, it is relatively recent in the history of the earth and its other inhabitants. Over the course of human history, there are landmarks and milestones that create a compelling historical narrative. The domestication of animals and plants to serve human needs was one such milestone that, through the lens of extended time, was associated with changes that transformed the ways humans lived as individuals, families, communities and societies. The continued and growing opportunities for previously unimaginable creativity and industry, where advances in knowledge and the sharing of knowledge, ideas, and technological innovations, resulted in the remarkable improvements in living conditions for the people of the time with increasing likelihood for survival of the individual and the collective. In this meteoric rise to power and domination of this planet, the history of the species is littered with artifacts that document this journey through time.

The earliest times are recognized by the discoveries of stones and bones that had been fashioned as tools for the survival for groups of individuals, because, after all, the species lives and thrives in groups. The groups could be of different sizes, the smallest being those of families or clans, that would hunt and forage for food. The earliest artifacts in stone are those presumably used for hunting and processing of animals successfully caught in the hunt [9]. With the advent of agriculture around 10,000 years ago, the groups became larger and the impact on the environment became greater [10]. The debris of the larger groups became more plentiful and varied as the need for shelter, equipment for agriculture, and for domestication animals grew. The nature of an agricultural community is such that not all people are involved all the time in planning for or actively seeking food, resulting in free time for creativity and productivity, which further added to the number of objects produced in that society. Indeed, it was the production and proliferation of artifacts in these societies that have enabled archeologists and anthropologists to extrapolate how the societies might have looked, lived and functioned. One of the earliest examples of environmental degradation was a consequence of repeatedly farming on a particular plot of land, which results in depletion of nutrients in the soil, that lowers the yield and contributes to soil erosion with negative effects on the natural flora and fauna in the settled area [11]. It is likely that early farming communities became aware of this phenomenon, as reference to it appears in the Biblical texts where there is a directive to work the land for six years then let it rest for the 7th or Sabbatical year, promising that it will increase the yield [12, 13].

The critical human need for water for personal consumption as well as for agriculture dictated that the early societies necessarily settled near sources of water, such as rivers, streams, or lakes. Two obvious examples in western history are the civilizations of Mesopotamia, which settled and flourished between the Tigris and Euphrates rivers, and in Egypt where the Nile provided water for agriculture, for human consumption, for transportation to support the society's physical and economic needs, and to serve as a domain for deities for society's spiritual needs. Bodies of water, particularly those that flow, also served in the convenient disposal of waste, inevitably resulting in the pollution and degradation of the water source with the risks of bacterial contamination. We know today from societies and communities living near water sources into which waste is disposed, that infectious diseases are a major health hazard, and that the most vulnerable are infants and young children who succumb to diarrhea, with consequent dehydration which is a major contributor to death, especially in low income developing countries in Africa and Asia to this day [14, 15].

In early agricultural times, communities were relatively small by today's standards, so the degrees of pollution and contamination may have been at a relatively modest scale. However, by the time of the Roman civilization in the western hemisphere approximately 2,000 years ago, city states had become quite large and sophisticated in the spheres of administration, engineering, architecture, politics and warfare, with the result that they were able to support larger populations. The city of Rome was built by the river Tiber, which provided the water and accepted the waste of the Roman society. Predictably, when the Roman population grew, more water was required, and more waste generated, which was channeled to the Tiber. As a result, the Tiber became dangerously polluted with a high concentration of bacteria and other toxins associated with the waste of that society in those days [10]. In order to satisfy the water needs of the people of Rome, engineers created aqueducts to bring clean water from the north to the city which became available to the population through the many fountains for which Rome is famous. The Romans, through their engineering ingenuity, not only channeled water from sources at higher elevations through a system of aqueducts, but developed a pipe system to carry the water to the fountains for domestic use for drinking as well as in their famous baths. They also developed toilets and sewage draining systems, which emptied into the rivers and the ocean. Roman pipes were constructed primarily from lead [16], which is a potent neurotoxin, particularly for children. So, not only would lead be found in the water for drinking and other domestic uses, but lead would also accumulate in the waste water that went into the Tiber. In addition, the pipes needed to be manufactured, which required fire and smelting. Lead fumes would inevitably be released into the air, eventually settling to the ground and found in the soil and sediment in the rivers. Furthermore, lead vapor and particulates were carried by winds far from the smelting source, to be found 2,000 years later in the analysis of a core of ice extracted from the subarctic ice cap in Greenland [17]. To this day, despite the banning of lead from gasoline and paint, it remains an environmental hazard as a result of the legacy of using lead pipes, recently creating a crisis involving lead-contaminated drinking water from the Flint river in Michigan [18].

Interestingly, the fall of the Roman Empire in 476 CE coincided with the ice core becoming relatively clean again, but not for too long. By the 16th century, the ice core reveals that the air on earth once again became contaminated and polluted with lead and other metals. That occurred when the Spanish Conquistadors defeated and subjugated the native peoples of South America and began to mine and extract silver and gold on a large scale. Their use of

large fires in smelting, released the fumes of metal into the South American air that also found its way into the ice caps hundreds of miles away in the Andes [19]. These examples of the Roman and the South American mining and metallurgic practices provide evidence that local pollution is not confined to local areas, but can be wide-spread, particularly where air and water are contaminated.

Another example of contamination of the air came from the large-scale domestication of livestock, presumably to feed the growing affluent populations with meat and milk and its products, such as cheese. Herding of domestic animals probably began around a similar time to the development of agriculture as a way of life and a way of supporting larger groups of people. Records on the condition of polar ice caps document a dramatic increase in the presence of methane gas around 2,000 years ago [20]. This increase was associated with the expansion in size of societies during the Roman Period, which coincided with growth in Chinese civilizations at the same time on the other side of the world. The increase in the presence of methane is considered to be a result of the emission of gases by the domestic livestock [21]. This period of high methane production subsided somewhat as the civilizations of the time fell to less organized groups. It rose again when greater degrees of social order were re-established during the middle ages and progressively through modern times as the growth in size of settled communities required more food. This necessitated the development of more agricultural lands and more livestock to feed the people, which in turn, resulted in the release of more methane gas. While low ambient levels of the gas may not play an appreciable role in modifying the climate, the larger amounts and concentrations in the air that have accumulated over the past half century have had a substantial and escalating effect on our climate as one of the ‘greenhouse gases’ [22].

INDUSTRIAL REVOLUTION

For the early centuries of writing, accessibility of reading matter was confined to the elite and educated. This changed dramatically with the invention of the printing press, which made written material readily available and accessible to the ordinary citizen in intelligible common vernacular, resulting in a burst of creative and cumulative advances in knowledge and technology. This coincided with the beginning of science and scientific experimentation that was ignited after the renaissance in Western society following the oppressive middle ages. The invention of machines and the establishment of factories in the late 18th and early 19th Centuries across Europe gave rise to the industrial revolution, which changed the course of human history.

In England, the plentiful presence of coal gave fuel to the fires of industry which was characterized by productivity and prosperity. The ideas, inventions and practices generated at that time were shared between countries and cultures to bring similar success and wealth to those countries. But along with the dramatic changes that brought success, there were unanticipated social, economic and environmental changes that were no less dramatic. The large-scale transformation of the society from being primarily agricultural to having a strong industrial base resulted in the movement of people from the rural areas into the cities where there were promising economic opportunities. This mass migration disrupted centuries of culture, community and socioeconomic balance to create a society with much wealth as well

as much poverty now concentrated in the cities, such as London, as captured so effectively in the novels by Charles Dickens.

At an environmental level, the burning of coal created significant air pollution which caused rampant respiratory problems, particularly among the poorer citizens who lived in the middle of this smoky toxic mix of pollution and poverty. The consequences of air pollution on health was noted relatively early in the process of industrialization, particularly in Great Britain where laws were progressively developed from as early as 13th Century when the use of coal in London was prohibited as being “prejudicial to health”, but really took off in the mid-19th Century to address the problem of coal burning and pollution [23]. However, it took an environmental disaster in London in December 1952, when 4,000 people died as a result of smog trapped in a thermal inversion, to bring about the United Kingdom’s (UK) Clean Air Act in 1956 [10, 23]. The phenomenon of the industrial revolution with its advances in technology, transportation and mass manufacturing as well as its unintended negative consequences, was not confined to the UK or Europe but was also advancing significantly in the US as well. On October 26, 1948 in the small industrial town of Donora, Pennsylvania, a weather anomaly in the form of a thick fog trapped malodorous toxic waste emissions from the town’s zinc smelting plant and stayed on the ground for five days [10]. Twenty people died and 7,000 were hospitalized with respiratory problems. The Donora disaster brought air pollution into focus in the United States, and paved the way for the Clean Air Act, established in 1970, and then amended in 1977 and 1990 [24]. One of the goals of the Clean Air Act was to address the public health and welfare risks posed by certain widespread air pollutants by setting pollutant standards coupled with directing the states to develop implementation plans, applicable to controlling industrial sources of pollution, in order to achieve these standards [25]. The pollution and health related problems as a result of industrialization and the use of fossil fuels are by no means over. Air pollution dramas continue to occur around the world, particularly in low- and middle-income countries, and in rapidly industrialising countries resulting in significant morbidity and mortality requiring urgent attention [26]. Air pollution from industrial sources consisting of gases and particulates not only leads to serious morbidity and mortality due to acute and chronic respiratory diseases as well as other disorders in exposed populations including an impact on reproductive health [27], but also contributes significantly to greenhouse gases and broader environmental consequences manifesting in climate change [28].

Smoke from coal-fired power plants also releases sulfur dioxide and nitrogen oxides into the air, which mixes with water and results in acid rain [29]. Corrosive and deadly to plants and trees, acid rain falls and drains into rivers, streams and lakes where it accumulates, polluting the water and altering the ecology by damaging the flora and fauna and rendering the water undrinkable in some areas. Furthermore, toxic by-products of coal burning, including mercury, are precipitated by rain and drain into waterways where, through biological transformation, the mercury enters the food chain and is consumed by fish where it bioaccumulates. Subsequent human consumption of mercury-infected fish can be toxic, especially to children and pregnant women, and can result in significant neurological damage [30]. The EPA regularly issues fish advisories that recommend which fish are to be avoided and which are safer to eat [31].

The relationship between the presence of mercury in fish and neurological damage of children became clear in the mid-1950s when an epidemic of children with severe neurological disorders was being seen in the clinics of the Chisso Corporation in Minamata

Bay, Japan. The disorders were eventually linked to the consumption of fish from the Minamata Bay, which were heavily contaminated with mercury. The mercury found in the fish was a result of the discharge of tons of mercury-containing waste into the Minamata Bay by the Chisso Chemical Corporation. There were an estimated 900 deaths attributed to the mercury poisoning and over 2,000 people who directly suffered from mercury poisoning [32]. This awareness has led to international efforts to reduce mercury levels in our environment through the Minamata Convention on Mercury [33].

This scenario has played out in the Great Lakes region of the US, which contains about one-fifth of the world's fresh surface water supply and nine-tenths of the US supply. Because the Lakes are part of a chain on the St. Lawrence waterway situated between the US and Canada feeding into the Atlantic Ocean, it has been ideal for shipping and transportation. For these reasons many factories and industries were established along the banks of the river and lakes so that the products of industry could be readily loaded onto large ocean-going vessels and shipped to harbors anywhere in the world. These industries discharged large quantities of toxic waste into the rivers and Great Lakes, creating substantial pollution, with the result that swimming and fishing in the rivers and lakes were prohibited [34]. The extent of pollution reached epic proportions in Lake Erie, the fourth-largest of the Great Lakes and the eleventh-largest globally if measured in terms of surface area. Lake Erie seemed to become more contaminated than the other Lakes, in part because of the location of industries along its shores, but also because the Lake is shallow and consequently less resilient. In addition to heavy contamination of Lake Erie, the Cuyahoga River, that runs through Cleveland, Ohio on the banks of Lake Erie, became so contaminated with a mix of pollutants, that it caught fire, presumably because of the oil slick on the surface of the river with other toxic chemicals and flammable debris from indiscriminate dumping of waste from steel factories, sewer disposals and larger scale littering saturating the river, ignited by a passing train that sent sparks into the oil-soaked river [35]. The Cuyahoga river did not just catch fire and burn once, it happened 13 times, the last time was in 1969. Although the fire of 1969 was not the most destructive or costly, for a variety of reasons, it was of high profile and, as a result, ultimately led to the creation of the EPA and passage of the Clean Water Act in 1972 [36, 37]. This Act established the basic structure for regulating pollutant discharges into the waters of the US and gave the EPA authority to implement pollution control programs such as setting wastewater standards for industry and maintaining existing requirements to set water quality standards for all contaminants in surface waters [38].

CHEMICAL REVOLUTION

During World War II (1939-1945), there was a compelling stimulus to science in the development of weapons of war and destruction on a diabolically grand scale. Each side in the conflict developed new technologies to gain military advantage in the seemingly endless battles that raged around the world. Innovations in machinery, aviation, metallurgy, explosives, chemicals and ultimately nuclear energy surged, and with these efforts came newer technologies that, after the end of the war, were turned to civilian commercial use and function in the new peacetime societies. Rapid development of the chemical industry led to newer chemicals and mass production to meet the needs of the recovering and fast-growing

post-war societies. All this activity helped to fuel the economy and bring increasing standards of living to many parts of the world, especially industrialized countries, while other, poorer parts of the world continued to suffer from societal disruption, ongoing conflicts, droughts, famines and exploitation, particularly for natural resources to feed the industrial needs.

One such chemical in this revolution was dichlorodiphenyltrichloroethane (DDT), which was developed to kill insects that plagued the crops of the farming industries [39]. This new pesticide was very effective and became widely distributed and used on a mass scale, being sprayed on large agricultural areas, often by airplane with ‘crop dusters.’ It was also used in suburban areas to promote greener lawns and, significantly in large parts of the world where insect borne diseases, like malaria, were endemic [40]. Therefore, not only did DDT help to increase agricultural yield but dramatically reduced the morbidity and mortality from malaria for people living in heavily insect-infested areas, particularly in the continents of Africa, Asia and Latin America. Unfortunately, the mass production and indiscriminate and injudicious use of DDT (and other chemicals), with the widespread dumping of the waste byproduct of chemical production, led to the chemicals leaching into the soil and waterways where they flowed into the rivers and streams and became part of the food cycle, having unintended consequences on the health of flora and fauna, from insects to birds, fish, amphibians, mammals and humans [39].

In 1962, Rachel Carson, who was an environmental scientist, wrote the book “*Silent Spring*”, an exposé condemning the indiscriminate use of long-lasting pesticides in general, and DDT in particular [41]. Her carefully researched material and its masterful presentation were the driving force behind the emerging environmental movement in the US and around the world. It is believed that many pollution control laws were influenced by “*Silent Spring*”. The use of DDT in many nations was subsequently banned. Globally, the use of DDT is limited and currently approved only for control of insect-borne diseases such as malaria, while safer alternatives are being researched. Despite the banning of DDT in the US, there is, however, a report that birds are dying in the area where the chemical company that had manufactured the pesticide was located in Michigan, presumably from residual DDT in the soil [42].

The widespread use of insecticides on crops has also had the unexpected and untoward effect of indiscriminately killing other insects that are beneficial to agriculture, particularly bees and other pollinators. The potential loss of this group of insects could have a dramatic impact on food production. The cause of the phenomenon of dramatic losses of bee populations, known as Colony Collapse Disorder, is, as yet, unclear and, according to the EPA, not necessarily exclusively the result of poisoning with pesticides [43], that climate change and other factors may be playing a significant role as well [44].

The story of DDT plays out in a similar pattern for tens of thousands of different chemicals that have been manufactured over the years, many of which have been demonstrated to be toxic to animals and humans, and tend to remain in the soil, water or even the air, long after manufacture has ceased. Part of the problem is that only a small percentage of the thousands of chemicals has been tested for safety, hopefully more will be tested in the future as a result of a chemical safety act which was passed in 2016 [45]. These chemical compounds are referred to as Persistent Organic Pollutants (POPs) because they are not readily biodegradable and can bioaccumulate in ecosystems, particularly in the food chain. POPs can be toxic to humans leading to increased cancer risk, reproductive disorders, alteration of the immune system, neurodevelopmental and neurobehavioral disorders,

endocrine disruption, genotoxicity and increased birth defects [46]. Just as with DDT, the POPs are of international concern as the chemicals are distributed globally. This challenge was addressed in the Stockholm Convention of 2001, the goal of which is ‘to protect human health and the environment from POPs [47].

Another distinct benefit to humans of the chemical revolution has been the discovery of increasingly effective medications in the treatment of human and animal diseases. This has been particularly effective at a global scale in the development of vaccines as protection against infectious diseases and the use of antibiotics in the treatment of infectious diseases. At the same time as the proliferation of increasingly potent antibiotics has been beneficial in treating the most recalcitrant infectious agents, widespread, often indiscriminate and, at times, injudicious uses of antibiotics by prescribers, has led to increasing resistance to existing antibiotics among bacteria and other microorganisms. The current challenge in modern hospitals is dealing with drug resistant bacteria, so-called ‘multi drug resistant organisms’ (MDRO), most notably the methicillin resistant staphylococcus aureus (MRSA) [48].

Antibiotics are also used in mass quantities in livestock farming to reduce risk of infection and promote healthier growth among the animals. This industrial-scale use of antibiotics in animals and widespread use of chemicals in agriculture, used to enhance human food supply, has played a part in modifying the human microbiome [49]. Connections are now being made between microbiota dysbiosis and a variety of different diseases such as rheumatoid arthritis, inflammatory bowel disease, type 1 diabetes, atopy, and obesity [50]. Over time, there are likely to be more conditions identified that are linked to the disturbance of the human microbiome.

Among the most useful yet concerning products of the chemical revolution are plastics [51]. The term “plastic” is derived from the Greek word “plastikos”, meaning fit for molding. It is an apt term because the products of the chemical process involving polymerization of basic carbon-based material are multiple in form and function. Plastics are used expansively in items in everyday use, from clothing to utensils to components of medical equipment, machinery and building materials, even spaceships. Indeed, our modern society is wedded to the use of plastics and plastic products. The problems for the environment come from several different levels of manufacture, use and after-use. In the manufacture, there are releases of harmful chemical compounds into the air. After-use and disposal of plastics, however, have created an environmental catastrophe. Because they are not biodegradable, they remain in our environment unchanged as pollutants in their original forms, as microplastics or larger pieces, such as plastic bottles and grocery bags. Although there is some recycling, most of used plastic products are found in waste sites like trash dumps, where they may become part of landfill, slowly degrading over millennia, or washed into waterways and into the oceans [52]. Each year, an estimated 18 billion pounds of plastic waste enters the world’s oceans from coastal regions where they can be ingested by small and large sea creatures endangering their lives and killing individual animals, as well as threatening species [53]. There is an estimated 100 million tons of plastic debris in our oceans at present, 80-90% of which has come from land-based sources which could have been recycled [54]. The use and disposal of plastic material is one of the challenges of our times. It is critical that we reduce consumption of single-use plastic objects; which is an appeal to consumers and manufactures to restrict the use of plastics, and for policy makers to pass laws regulate the use of certain plastics as well as on the need to recycle. The bigger challenge is the cleanup and removal of plastic debris

particularly from shorelines [55] and of the massive floating islands of plastic in the world's oceans [56].

Apart from the global challenge of plastic pollution, there is a real threat to human health, particularly for children who are more vulnerable because their organ systems are developing, especially the brain, endocrine and immune systems [57]. Concerns have long been documented and a list of specific hazardous chemicals associated with production of plastics is growing [58].

WASTE DISPOSAL

The impact of gravity and the relatively porous nature of the earth's soil results in accumulation of chemicals and substances in the soil and, with rains, they are likely to seep into the water table beneath the surface and into the rivers and streams. When the amount of chemical pollutant is great, the potential saturation of the soil can be correspondingly great and last for a long time, posing significant risks to life for people and animals. A notable dramatic example of this scenario took place at Love Canal in New York in the late 1970s, which has been described as one of the "most appalling environmental tragedies in American history" [59, 60]. In the early part of the 20th Century, William T Love imagined a model community in New York, on the edge of Niagara Falls and dug a canal to supply water power to what he envisioned would be a combination of industrial and residential areas in the community. Unfortunately, his dream was not fulfilled, and the empty canal was then filled with approximately 21,000 tons of toxic chemical waste from the Hooker Chemical Company. The city of Niagara Falls then built houses and an elementary school on the site. Over the years, the underground containers filled with of chemical waste corroded and, in 1977, after record rainfall, chemicals leaked into the soil. Dissolved chemicals leached into people's homes, backyards, and playgrounds, resulting in serious adverse health effects in the community, with high rates of birth defects and miscarriages [59].

As a result of this tragedy, the US Congress enacted the Comprehensive Environmental Response, Compensation and Liability Act to address toxic waste dumps [61]. This became known as the Superfund Program which is designed to protect human health and the environment by cleaning up polluted sites, make responsible parties pay for cleanup work, involve communities in the Superfund process, and return the Superfund sites to productive use [62]. In addition, in 1995, the EPA launched the Brownfields program "to empower states, communities, and other stakeholders in economic redevelopment to work together in a timely manner to prevent, assess, safely clean up, and sustainably reuse" land which may be complicated by the presence or potential presence of a hazardous substance, pollutant, or contaminant [63]. Examples of the Brownfields programs were provided earlier in the discussion on the revitalization of the city of Atlanta with the Atlantic Station and Beltline projects [6, 7]. Of note is that as part of the decision criterion for the Atlanta Beltline Brownfield redevelopment project, a health-impact assessment was conducted to look at how the proposed changes in access and equity, environmental quality, safety, social capital, and physical activity would maximize health benefits and reduce negative effects [64]. The findings were ultimately incorporated into the design to fulfill the EPA Ecosystems Services model (Figure 1) [8].

The disposal of waste is not necessarily confined to a neighboring location or regional site. Because of the large-scale generation of toxic waste by industrialized countries, it had become a practice to transport waste from the high income industrial countries to low income developing countries adding to their toxic burdens [65]. Although historically, there has been relatively limited regulation on this transaction, the EPA notes that several international agreements address transboundary transportations of hazardous waste including the Basel Convention [66], the Organization for Economic Cooperation and Development (OECD) Council Decision, and local and regional agreements such as exist between the United States and Canada, Mexico, Costa Rica, Malaysia, and the Philippines [67].

NUCLEAR AGE

In addition to the proliferation of chemical production during and after World War II, there was the discovery that the phenomenon of nuclear fission could be applied to and used in weapons of mass destruction, far greater than had been previously imagined. The testing of these devices took place in the desert in the Southwest US, on tropical islands in the Pacific Ocean and in the atmosphere, resulting in such powerful explosions that it surprised and shocked even the scientists charged with developing them [68]. Neither did scientists predict the destructive impact of the radiation released from these atomic devices on plant and animal life far from the site of the explosion. At test locations in the Pacific, not only was there total destruction of ecology of the islands, but the inhabitants of the islands were subjected to dangerous levels of radiation, and they remain displaced and disenfranchised to this day as they continue to suffer adverse health consequences [68, 69]. The use of the atomic bomb by the US during the war resulted in the almost total destruction of the Japanese cities of Hiroshima and Nagasaki and the immediate death of over 200,000 citizens near the epicenters of the explosions, as well as the deaths of those within range from acute radiation sickness. Those further away from the epicenter suffered long-term adverse health consequences [70].

The adoption of the nuclear option in war then became part of the weapons manufacture and proliferation in the US and in the Union of Soviet Socialist Republics (USSR), or the Soviet Union, during the ‘Cold War’. These two so-called Super Powers accumulated nuclear stockpiles for more than four decades following the end of World War II, which posed an existential threat to human survival. The threat of mutual annihilation, so-called ‘Mutually Assured Destruction’, or the appropriate acronym MAD, was a term attributed to John Von Neuman [71], one of the prominent scientists of the time and part of the team that developed the hydrogen bomb. This insanity came to an end with the mutually agreed limitations in use of nuclear weapons, starting with the Strategic Arms Limitations Treaties (SALT) between the leaders to the US and USSR [72]. The United Nations Office for Disarmament Affairs enacted a number of treaties progressively addressing the control of nuclear weapons, including the Treaty on the Non-Proliferation of Nuclear Weapons in 1968 and, most recently, the Treaty on the Prohibition of Nuclear Weapons in 2017 to prevent destruction of life and the environment [72, 73].

After the dramatic use of the Atomic Bomb and its consequences, attention was turned to peaceful use of nuclear energy in the generation of electricity and nuclear power plants were developed in the 1950s by both the USSR and the US [74]. Once hailed as a safe

source of energy, human exploration of nuclear power has come with substantial and dramatic risk. In April 26, 1986, a sudden surge of power during a reactor systems test destroyed Unit 4 of the nuclear power station at Chernobyl, Ukraine, in the former Soviet Union, releasing massive amounts of radioactive material into the environment [75]. The consequent mortality and morbidity of the disaster resulted in the deaths of 28 workers in the first four months with another 106 workers received high enough doses to cause acute radiation sickness. In the immediate aftermath of the disaster many children in the area drank milk contaminated with radioactive iodine, which resulted in a high rate of thyroid cancers among the children among other long term adverse health effects on the population, however, it was the long-term psycho-social impacts on residents and evacuees from the disaster that has been the greatest realization with findings of higher rates of depression, alcoholism and anxiety, with negative self-assessments of health, as well as unexplained physical symptoms [76].

There have been other nuclear accidents of a similar nature, such as the Three Mile Island commercial nuclear power plant partial meltdown in 1979 in the US [77], and, in 2011, following a massive earthquake and tsunami affecting Japan, the Fukushima Nuclear Reactor was damaged resulting in release of radioactive material [78]. Neither of these accidents had the same consequences as the Chernobyl disaster, but they certainly raised alarm and concern of the risks of nuclear power plants.

Overall, the resultant increase in atmospheric radiation and radioactive isotopes from all sources has the potential for adverse health outcomes, especially for children [79]. Furthermore, the disposal of hazardous radioactive waste remains a grave concern in avoiding human exposure and reducing the likelihood of environmental damage especially to flora and fauna. There are very clear criteria for how the waste is stored, depending on the half-life of the particular radioactive material and the levels of waste being of low, intermediate or high, which will determine how and where the waste is stored. Although the criteria are accepted globally, each country is responsible for its own details of management [80], the potential risk remains.

SOIL DEGRADATION

Soil degradation of the land likely began in early agricultural times when repeated farming of the same plot of land resulted in degradation of the quality of the soil. As mentioned above, this phenomenon was recognized in biblical writings, with the requirement to work a particular field for a limited number of years then allowing the land to replenish its nutrients for year before resuming farming [12, 13]. There is speculation that the Akkadian Empire which ruled the region between the Tigris and Euphrates rivers four millennia ago, may have collapsed as a result of soil exhaustion and desertification, the process of making a desert of previously fertile soil [81]. Soil degradation and desertification is of grave concern in sub-Saharan Africa, as it seriously depresses food production and, along with other dramatic unpredictable climate events, like droughts and floods, increases the likelihood of food insecurity and famine [82]. Famine can lead to restive populations and large-scale migration to find food and work, which can destabilize not only the local and neighboring communities, but beyond country borders as famine-affected refugees [83]. In recent years, wars, drought and famine have caused refugee migration from Africa and the Middle East to

Europe, which has dramatically altered political and social dynamics within and between countries, and appears likely to play out again as the impact of climate change will continue to affect weather patterns and hence the quality of the soil which affects agriculture and food production [84].

Figure 2. Global tree cover loss rose 51 percent in 2016 [85].

The other major impact on the quality of soil by human activity is the process of deforestation which has dramatically increased in pace and magnitude (see Figure 2) [85]. The consequences of deforestation, particularly in the large rain forests of Brazil, and equatorial Africa, not only results in degradation of the soil causing erosion but increases the risk of desertification [86]. As an example, natural forests in Indonesia have been destroyed by burning, for mining and natural resources as well as for monoculture of palm oil groves for the yield of the fruit [87]. This large-scale deforestation and widespread destruction of critical vegetation in our ecological balance has drastically reduced the natural source of carbon dioxide consumption and oxygen generation resulting in an increase in atmospheric carbon dioxide which is a 'greenhouse gas' and major contributor to climate change. In addition, as a result of the disruption of the local ecology, there is an increased risk for floods, mudslides and forest fires which further aggravate the situation [88]. The changes in natural forests especially rain forests are sadly also resulting in a reduction in biodiversity [89].

CLIMATE CHANGE

The rather narrow range of atmospheric temperatures on Earth has resulted in the proliferation of plant and animal life in the waters of the rivers, lakes and oceans, as well as on the land and in the air. For all life on this planet there is a temperature range from summer to winter and day to night for comfortable survival and maintenance of the Earth's homeostatic and current ecological character.

Over the course of the past two millennia, but particularly in the past 150 years, and rapidly accelerating in the past 70 years, human activity has progressively and cumulatively changed the climate on earth by the burning of coal and other fossil fuels, particularly in

industry, by the emissions of exhaust gases from the consumption of gasoline as a result of the increasing number of motor vehicles, by the emission of methane gas from livestock, and by deforestation. At present there is overwhelming evidence that we are experiencing dramatic climate change associated with global warming that is distinctly related to human activity [90].

According to NASA's Goddard Institute for Space Studies (GISS), the average global temperature on Earth has increased by about 0.8° Celsius (1.4° Fahrenheit) since 1880. Two-thirds of the warming has occurred since 1975, at a rate of roughly 0.15-0.20°C per decade see Figure 3 [91].

Figure 3. Annual temperature from 1951-present vs average between 1951-1980 [91].

As the world population of humans increases exponentially, there is a greater impact on the earth, with the result that the land, waters and atmosphere are becoming attenuated, and the natural flora and fauna of the Earth's biosphere are increasingly threatened. At the same time, there is a growing need to assure adequate food production and a critical need to feed the increasing number of people in the world. This is a compelling reason to take immediate action to reverse current trends in order to secure a more settled ecological homeostasis.

Another consequence of climate change and warming of the planet, is a dramatic change in the occurrence, frequency and intensity of extreme weather phenomena, such as heat waves, droughts, hurricanes, floods, snowstorms, and wildfires [92]. Not only do these disasters cause destruction and devastation to the built environment, but the after-effects on the natural and built environment, with disruption of communities, all come at a high financial toll.

The health impacts of the extreme weather events can result in immediate deaths or serious physical injuries or illnesses and disabilities that can appreciably reduce functional well-being and life expectancy, as well as have an impact on mental health of individuals, families and communities [93]. Significantly, the progressive changes wrought by the rising global temperatures affect the ecological and ecosystem balance manifesting in changes in ambient temperature and humidity, air quality, water quality, and agricultural conditions that have implications on food production and food security, as well as alter the insect and microbial populations resulting in increases in human diseases and mental health consequences (see figure 4).

Figure 4. Climate change and health [93].

These health impacts fall most heavily on vulnerable populations, especially children, pregnant women, older adults, low income groups, some communities of color, immigrant groups, Indigenous peoples, persons with disabilities, and persons with preexisting or chronic medical conditions. Furthermore, at a global level, the most vulnerable populations tend to live in high-density communities in areas that are also more vulnerable to floods and, as a consequence, suffer great losses of life. The concern is that, as the global temperatures continue to rise and extreme weather phenomena occur more frequently, the cumulative consequences, particularly on health, has significant implications on development of health policy [94].

BREAKING THE CYCLE

This exploration of the cycle of environmental degradation began with an examination of the microcosm of the Proctor Creek neighborhood in Atlanta. The lessons of the Proctor Creek experience demonstrate the critical importance of a consortium of concerned participants with an understanding of the situation, with ideas on how to break the cycle, with financial resources and a determination and commitment to work together to make changes for the good of all [1].

Just as the citizens of the Proctor Creek community took action to clean up their creek and restore an environment that is clean, pleasant and healthy, there are a multitude of similar efforts at many levels in neighborhoods, towns, states, countries and globally that have successfully broken the cycle of environmental degradation and restored a healthier ecological balance. In many places, these efforts have enhanced opportunities for healthier

physical, emotional and social activities for the citizens, characterized by the EPA as Ecosystems Services (see figure 1). Figure 5 represents a conceptual model of how the natural environment becomes degraded and how efforts to break the cycle can reverse the trend towards a more natural and healthy ecological balance.

Figure 5. Diagram depicting the process of environmental degradation followed by regeneration through environmental stewardship.

Efforts to break the cycle can and do occur at many different levels including a personal commitment to reduce waste by not using single use plastics, by driving cars that do not use fossil fuels, by recycling, and many other changes to personal behavior that are sensitive to the environment, and by extending the commitment to local community action, and advocating national and international governing bodies to likewise take up the charge and develop strategies to make positive changes and laws to assure maintenance and compliance with the standards expected for a healthy environment. Each organization and agency, government or Non-Governmental Organization (NGO), or international body, plays a significant role in the process. The greater the number of entities involved, and the greater the interaction and coordination among them, and the greater the resolve, the greater will be the impact on improving the health and well-being of all living beings and of the ecological balance of our planet. In this context, three examples of bodies whose missions and visions to make a difference are worthy of our support are offered for consideration.

THE UNITED STATES ENVIRONMENTAL PROTECTION AGENCY (EPA)

The mission of EPA is to protect human health and the environment. EPA's Strategic Plan identifies the measurable environmental and human health outcomes the public can expect from EPA and describes how the EPA intends to achieve those results [95].

In 1970, as a result of heightened public concerns about deteriorating city air, natural areas littered with debris, and urban water supplies contaminated with dangerous impurities, the EPA was formed [37]. At the time, given the dramatic environmental realities of air pollution, water pollution and pollution of the soil, President Richard Nixon requested billions of dollars of funding for a rather far reaching and visionary set of challenges:

- setting national air quality standards and stringent guidelines to lower motor vehicle emissions;
- launching federally-funded research to reduce automobile pollution;
- ordering a clean-up of federal facilities that had fouled air and water;
- seeking legislation to end the dumping of wastes into the Great Lakes;
- proposing a tax on lead additives in gasoline;
- forwarding to Congress a plan to tighten safeguards on the seaborne transportation of oil; and
- approving a National Contingency Plan for the treatment of oil spills.

In order to achieve these goals, the EPA was given the following mandates [37]:

- The EPA would have the capacity to do research on important pollutants irrespective of the media in which they appear, and on the impact of these pollutants on the total environment.
- Both by itself and together with other agencies, the EPA would monitor the condition of the environment, biological as well as physical.
- With these data, the EPA would be able to establish quantitative "environmental baselines", critical for efforts to measure adequately the success or failure of pollution abatement efforts.
- The EPA would be able, in concert with the states, to set and enforce standards for air and water quality and for individual pollutants.
- Industries seeking to minimize the adverse impact of their activities on the environment would be assured of consistent standards covering the full range of their waste disposal problems.
- As states developed and expanded their own pollution control programs, they would be able to look to one agency to support their efforts with financial and technical assistance and training.

In the almost 50 years since its inception, the EPA has played a significant role in improving the quality of our environment, with cleaner air, cleaner water and strategies to clean up polluted lands. It has also responded to the impact of natural disasters such as Hurricane Katrina in New Orleans, and man-made disasters such as the 2001 destruction of the World Trade Centers in New York. It has also worked collaboratively with international

organizations to help make positive changes in the environment around the world. Significantly, it has worked with the international community to address the challenges of climate change, despite the changing stances of the leadership in the US [96]. Unfortunately, changing leadership in the US affects the philosophy and policy of the EPA so that the path forward is not necessarily a straight one, but deviates, at times from its core mission. This situation requires constant vigilance by concerned citizens and organizations who monitor the environment and the impact of the environment on health, especially for children and other vulnerable populations.

THE WORLD BODY: UNITED NATIONS (UN) AND WORLD HEALTH ORGANIZATION (WHO)

Both the UN and the WHO are intimately involved in improving the environment towards improving the health of all people in the world.

The WHO's Health and the Environment [97] program mandate is to support Member States to improve health outcomes linked to environmental risks such as:

- Unsafe water and inadequate sanitation
- Poor indoor and outdoor air quality
- Exposure to toxic or hazardous waste and chemicals
- Climate change

The 2017 annual report of the UN Environment states [98]:

“Throughout the past year, UN Environment campaigned on many fronts against the spiraling pollution of air, water and land around the world. Climate change, wildlife crime, micro-plastic pollution and land degradation are just a few examples of environmental ills that affect the health and well-being of communities and economies, global efforts to achieve the Sustainable Development Goals and even the security of nations.”

UNITED NATIONS FRAMEWORK CONVENTION ON CLIMATE CHANGE (UNFCCC)

The United Nations Framework Convention on Climate Change (UNFCCC) is an international environmental treaty adopted in 1992 and signed at the Earth Summit in Rio de Janeiro, Brazil to “stabilize greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system” [99]

The UNFCCC serves as the foundation of an evolving global climate effort and sets a long-term objective of avoiding dangerous human interference with the climate system. Toward that end, the agreement:

- commits all nations to take steps to mitigate greenhouse gas emissions;
- establishes the principle of “common but differentiated responsibilities and respective capabilities” (CBDRRC), recognizing that countries vary in their

contributions to climate change and capacities to address it, so their obligations will likewise vary; and

- commits developed countries to assist developing countries in reducing emissions and coping with climate impacts.

There have been a number of international meetings, initially in Kyoto, Japan in 1995, where the Kyoto Protocol was developed, followed by the Paris Agreement in 2015 and most recently in Katowice Poland in 2018. Although these successive conferences have affirmed the commitment of participants to respond to the real and immanent dangers of climate change, there are so many competing factions among different nations and within each of the countries, that the resolve melts away while there remains much to do as the time slips away.

CONCLUSION

Over the millennia of human habitation on this planet, we have multiplied and conquered the land, seas and air. In the process, we have exploited the Earth's natural resources and irrevocably altered the quality of the natural environment to the detriment of almost all living beings. Human-caused environmental degradation has been progressive and cumulative and creates an existential threat that must be addressed. Rising global temperatures and consequent ecological changes are scientifically irrefutable. In this commentary, some of the more dramatic elements, episodes and disasters have been presented and discussed with meaningful responses at local, national and international levels being highlighted.

The continued threat of environmental degradation to our health and, arguably, to human existence and the deepening disruption of the ecology of our planet, compel further immediate and sustained action. Historically, we have been more reactive than strategic in our approach, responding to environmental disasters and the immediate consequences. While these responses have been, in many instances, demonstrably effective, they fall short of a broader approach to environmental degradation with a longer view. Our objective must be to avoid the disaster and our public policy and practice must be informed by science and dedicated to environmental recovery.

In order for humans to continue to flourish on Earth, we must acknowledge the link between the environment and health, human health and the health of all other living species, and on the ecological health of our planet. We must continue to reverse the trends of environmental degradation and the local, regional, national, international and global realities that accompany it. As outlined in this commentary and captured in figure 4, actions can be taken by individuals, groups of individuals or by larger organizations and agencies, to break the cycle of environmental degradation and improve the quality of our environment to assure the health and viability for all species in our current ecological system for the future. We must build on the successes of, and lessons learned by previous generations, dedicate ourselves to the depth of contributions we will make, and leave a legacy and a positive direction for the generations who will follow us. *It is not incumbent upon on any one of us to finish the task, but neither are any of us free to absolve ourselves from the undertaking of it.* [100]

ACKNOWLEDGMENTS

I would like to thank my good friend and critical editor David Ervin for his able assistance in helping to make the text more coherent and comprehensible. I would also like to thank Martha Berger, Ruth Etzel, Ben Gitterman and Laura Anderko for their meaningful and valuable comments and suggestions. Also, thanks to my family, friends and colleagues for the many discussions that have provided the ideas and information around this topic. This publication was supported by the cooperative agreement award number 5 NU61TS000237-05 from the Agency for Toxic Substances and Disease Registry (ATSDR). Its contents are the responsibility of the authors and do not necessarily represent the official views of the Agency for Toxic Substances and Disease Registry (ATSDR). ABSTRACT

In this chapter we aimed to identify the impact of psychosocial risk factors on pregnancy outcomes for high risk women in an urban setting. Women in this category tend to experience adverse pregnancy outcomes, like preeclampsia, at greater rates than low or medium risk women. A retrospective paper chart review of East Harlem women served by LSA Family Health Service (LSA) Maternal Outreach Program (MOP) was conducted. All women who enrolled in the MOP with a singleton pregnancy from January 2015 to December 2017, were eligible for inclusion in our analyses. Data were analyzed using SPSS (version 23). Of 379 total charts reviewed, 68.6% (n=203) were Hispanic/Latina women, 44.8% (n=163) were English only speakers, 67.4% (n=226) were identified as overweight/obese, 90.6% (n=328) were mothers over the age of 20 among those for whom data were available. Sixty-two percent (n=235) initiated prenatal care in their first trimester, and 71.5% (n=271) were referred to the MOP by a hospital or other healthcare provider. The percentage of preeclampsia among mothers was 26.9% (n=102). After adjustment for type of LSA services received, and race/ethnicity, there were no associations between psychosocial risk factors and preeclampsia diagnosis in this population. Further research is needed on the relationship between psychosocial risk

factors and preeclampsia to identify potential areas of intervention and reduce the burden of disease.

INTRODUCTION

Preeclampsia is a disorder of pregnancy that is characterized by new onset hypertension along with cerebral or visual symptoms, pulmonary edema or laboratory abnormalities indicating thrombocytopenia, transaminitis or renal dysfunction, during pregnancy or immediately postpartum [1]. The diagnosis can be present at any stage of gestation but is more commonly encountered in the third trimester or up to six weeks postpartum [2]. The prevalence of preeclampsia and other pregnancy related hypertensive disorders is estimated to be between 2-8% globally [3-5]. Hypertensive pregnancy disorders are responsible for more than one quarter of maternal deaths in Latin America and the Caribbean [3]. In the United States, racial and ethnic disparities in the prevalence of preeclampsia persist. One study found that Mexican American women had higher preeclampsia rates compared to non-Hispanic White and East Asian women [6]. Another study of pregnant New York City women found that among women with pre-existing diabetes, Hispanic and non-Hispanic Black women were more likely to have preeclampsia than non-Hispanic White women after adjustment for confounders [7].

Hospital discharge data show that African American women have higher rates of and more severe preeclampsia compared to other racial and ethnic groups [8]. Known risk factors for preeclampsia include: nulliparity, chronic hypertension, diabetes and obesity [9-10]. Mothers younger than 20 years or older than 35 years of age are also more likely to be diagnosed with preeclampsia [10]. Preeclampsia is associated with poorer birth outcomes such as increased likelihood of having a preterm or low birth weight infant, since delivery via induction of labor continues to be the mainstay of treatment for affected women [11-12]. Although the maternal comorbidities associated with this disorder have been well documented, there is less research on the psychosocial risk factors associated with this important pregnancy complication. The purpose of our descriptive study is to identify social risk factors for preeclampsia in a high-risk cohort of mothers who received skilled home nursing visits through the Maternal Outreach Program (MOP) at LSA Family Health Service (LSA) to identify additional areas for intervention.

OUR STUDY

LSA Family Health Service (LSA) is a non-profit community organization located in East Harlem, New York. This neighborhood has historically been the home to several immigrant communities, becoming one of the largest minority communities in New York City with more than three quarters of the population identifying as Latino/Hispanic or Black/African American [13]. The median income is approximately \$38,000 in both East and Central Harlem with about 30% of residents living below the federal poverty level [14-15]. This organization provides social and health services to address many aspects of family health; and is designed to empower those who are vulnerable and have limited access to

necessary resources needed to cultivate a healthy life. The LSA Maternal Outreach Program (MOP) consists of a team of community nurses who provide care to prenatal and postpartum women residing in East and Central Harlem by conducting home-visits and providing individualized prenatal and infant care education as well as breastfeeding classes. Additional services provided by LSA to promote community health/wellness and family support include: The Advocacy and Food Pantry Program, Environmental Health Services, Parenting and Child Development, and Preventive Services—a support program that works to strengthen fragile or crisis-impacted families.

The study population consisted of pregnant and postpartum women served by LSA. Women were referred to the MOP if there was a perceived need and potential benefit from receiving home nursing care and community support. Women also self-referred if interested, based on community awareness of the organization and services offered. All women with singleton pregnancies, who were clients of the MOP during 2015-2017, were eligible for inclusion in our study.

*Of the participants for whom data were available.

A retrospective paper chart review of program data on mother-infant dyads was conducted by trained research assistants. Data were analyzed with SPSS software (SPSS version 23). Chi square analyses and logistic regression were used to model associations between preeclampsia and psychosocial risk factors identified by the nurses during program intake. Risk factors of interest included: being a teen or inexperienced parent, (defined as

being a mother less than 20 years or being a first time mother); having food insecurity, insufficient income; low maternal education, (defined as less than a 10th grade education or leaving school before age 17), poor housing quality, and perceived neighborhood safety.

OUR FINDINGS

The study population consisted of a total of 379 mothers with singleton pregnancies. More than two thirds of the women (n=257) were enrolled in the postpartum-only component of the MOP. About one quarter (n=94), enrolled in both the prenatal and postpartum components of the MOP. Less than 10% (n=28) participated in the prenatal program only. Table 1 summarizes the demographic information of the MOP participants stratified by type of LSA services received. More than two thirds (68.6%) of the women identified as Latina and, 28% were African American. The group of women who received only postpartum services had the lowest percentage of Latina women (57.9%) and the highest percentage of Black women (37.7%) compared to the other groups ($p<0.001$). The postpartum only group also had the highest percentage of women who spoke primarily English (56.8%). In comparison, the group with the highest percentage of Spanish only speakers, was the prenatal-postpartum group (56.4%). BMI was elevated in about two thirds of the women in all three groups with minimal between group differences. Eighty-seven percent of women enrolled in the postpartum-only program were referred by a hospital or clinic compared to less than 40% in the prenatal only and prenatal-postpartum participants of the MOP combined.

Table 2 outlines the prevalence of our psychosocial risk factors by LSA service type. Generally, participants who were only enrolled in the postpartum program were the least likely to report low maternal education, food insecurity, insufficient income, substandard housing quality and living in a high risk or unsafe neighborhood (all $p < 0.001$).

PREECLAMPSIA IN THE MOP

Table 3 summarizes the percentage of women with preeclampsia by psychosocial risk factor, stratified by type of LSA services received. Preeclampsia rates were lower among women with less maternal education (13.6% vs 30.5%, $p = 0.002$) and those with poor housing (17.5% vs 29.9%, $p = 0.018$). Table 4 highlights the odds of preeclampsia in clients of the MOP with select risk factors. Consistent with the findings in Table 3, the odds of preeclampsia were 64% lower in women with low maternal education (OR 0.36, 95%CI 0.19-0.70) and 50% lower in women who lived in poor quality housing (OR 0.50, 95%CI 0.28-0.89). However, after adjustment for race/ethnicity and type of LSA services received, these differences were no longer statistically significant (Adj OR 0.53, 95%CI 0.24-1.13 and Adj OR 0.67, 95% CI 0.32-1.38). There were no statistically significant associations between preeclampsia and food insecurity, income, teen/inexperienced parenting or perceived neighborhood safety.

Table 4. Odds of preeclampsia by psychosocial risk factor

	Unadjusted OR (95%CI)	Partially Adjusted OR (95%CI) ^a	Adjusted OR ^b (95%CI)

DISCUSSION

The present study is among the first to explore the potential impacts of various psychosocial risk factors on preeclampsia for an at-risk, minority population receiving skilled home nursing visits. Demographic analysis of our study population confirms that the MOP at LSA serves a high-risk population. The group was primarily comprised of English-speaking Latina women categorized into overweight and obese groups by their calculated BMI, which is consistent with previous research identifying an increased risk of preeclampsia in women with this risk factor [16].

Figure 1. Areas in the cycle of health disparities targeted by LSAFHS.

Fewer women in the teen/inexperienced parent category had a diagnosis of preeclampsia, but this relationship was not significant after adjustment for race/ethnicity and type of LSA

service received. These results differ from existing literature on teen and inexperienced parenting as a preeclampsia risk factor. Other studies have associated young maternal age (under 20 years old), with an increased risk of preeclampsia, especially among racial and ethnic minorities [17]. LSA's definition of 'inexperienced parent' also includes nulliparous women who may have more anticipated stress related to preparation for becoming a first-time parent. There is literature which suggests that perceived stress and nulliparity may be associated with the development of preeclampsia during pregnancy [18-19]. The LSA category for teen and inexperienced parents was a combination of these two populations. Therefore, it is possible that the association between teen parenting and preeclampsia, as well as the association between parenting experience and preeclampsia, may have been masked. Further research should explore teen parenting, parenting experience and parental stress as individual risk factors for this disorder within this population. Women with low maternal education also had lower rates of preeclampsia. However, this relationship appeared to be explained by differences in the distributions of LSA service type and race/ethnicity. This finding disagrees with existing works that associate low maternal education with a greater risk of preeclampsia [19-20]. One possible explanation is differences by nativity status. Foreign-born women tend to have better birth outcomes than those born in the United States regardless of racial or ethnic background [21]. Therefore, a study population with a higher percentage of foreign-born women may have lower education but better birth outcomes nonetheless. Nativity was beyond the scope of our data analyses.

Teen/Inexperienced parent: Mother less than 20 years of age, or being a first time mother.
Low maternal education: Mother who left school before age 17 or had less than 10 th grade education.
Food insecurity: Defined as a report of not enough food or only nutritionally deficient food in the home.
Insufficient income: Not enough income to meet basic needs such as food, housing, healthcare and supplies.
High-risk/unsafe neighborhood: Perceived presence of or concern for safety in the building where they reside.
Substandard Housing: Presence of less than adequate housing conditions such as apartment or building fixtures in poor condition, non-functioning windows, deteriorating flooring and walls.

Figure 2. Risk factor definitions used by LSAFHS nurses.

We did not find any significant association between nurse-reported insufficient income or food insecurity and having preeclampsia. This too, is in contrast with relevant literature that cites low socioeconomic status as being positively associated with preeclampsia development [22]. Household income data were not available for analyses so we were unable to identify discrepancies between mothers' perceived income insufficiency, and measured income that could have provided additional insight into our findings. It is possible that the mothers' perception of whether the household income was sufficient may not have correlated well with their true income. Additional research with more direct, quantitative measures of income insufficiency is warranted. Similarly, there were no differences in preeclampsia rates among those who reported and those who did not report food insecurity. One explanation is that the nurses' intake form did not note the type of food that was available at home or the nutritional content of what the women ate. Research shows that risk of preeclampsia may be increased by diets that are high in fat or deficient in calcium [23-24]. Other studies suggest that

increased intake of added sugars is associated with the development of preeclampsia [25]. Therefore, mothers with preeclampsia may have had access to a greater quantity of food of poorer quality which may have impacted our results.

After adjustment for the covariates, there was no significant association between housing quality or neighborhood safety and preeclampsia. Established literature cites that residents who live in substandard housing are more likely to have additional socioeconomic risk factors, such as living in an unsafe neighborhood that increase levels of chronic stress and poorer mental health, which then increases risk of adverse birth outcomes, including preeclampsia [26]. While this study's results diverge from these findings, it is possible that these two risk factors are less important than medical comorbidities risk factors, like BMI. The distribution of BMI was similar among the three groups of women and modelling BMI in relation to preeclampsia was beyond the scope of our analysis. Alternatively, the risk factor definition may have been too heterogeneous to identify specific environmental housing factors that are associated with preeclampsia.

Of great significance is the finding that women who only participated in the postpartum component were by far more likely to be referred by health care providers for medical conditions. Many of these women had preeclampsia as the referral diagnosis, which is reflected in our data since the postpartum-only group had the highest preeclampsia percentage overall. Though they had higher rates of protective risk factors for preeclampsia, such as higher maternal education level and more income, they were also more likely to identify as Black or African American which is a well-documented preeclampsia risk factor [8, 27]. Most of these women did initiate prenatal care within their first trimester but were not referred to MOP for secondary preventive care. This highlights a gap in referrals for participants and a failure to identify high-risk women for additional support for preeclampsia earlier in their pregnancy. Potential reasons for lack of referral include lack of provider awareness of MOP, patient preference, or competing priorities especially for medically complex or hospitalized mothers and infants. Since preeclampsia is associated with both maternal and infant comorbidity, early detection and disease management are public health priorities. Referrals to skilled, home nursing programs that connect clients to community resources could mitigate some of the adverse outcomes associated with this disorder; and serve as an additional window of opportunity to decrease the maternal and child health disparity gap.

Our study has several limitations, including the small sample size after stratification by program type and risk factors; and the lack of validation of the LSA criteria used for the different psychosocial and environmental risk factors. Other challenges include the inability to assess inter-observer reliability amongst the nurses and members of the data collection teams, as well as the lack of specificity in criteria used to define some of the risk factors of interest.

Nevertheless, we did demonstrate the ability of a community-based organization to track data with great public health significance in a systematic way and provide much needed home-base services during and after pregnancy. The neighborhood served by the MOP has a significant proportion of mothers who often have less access to traditional health care venues and our study contributes to the body of literature on this important population. Additional pilot projects could explore ways of helping community-based organizations improve their data management strategies in a self-sustaining way; and increase their capacity to evaluate their program outcomes and further identify need gaps for the populations they serve.

CONCLUSION

We found no association between any of the psychosocial risk factors examined and preeclampsia, after adjustment for race/ethnicity and the type of MOP services received in our population. Though our findings differ from existing literature, they do highlight the importance of carefully considering the criteria used to screen mothers for common risk factors. Further research is still needed to better characterize risk; and to reveal additional links between socioeconomic factors and preeclampsia. Given the long-term negative consequences of this disorder for both mothers and infants, understanding the environmental risk factors for this condition is critical in order to break the cycle of birth outcome disparities in ethnic minority communities. Many of the root causes of maternal and child health disparities are challenging to solve; and organizations like LSA provide much needed support and care to marginalized communities.

ACKNOWLEDGMENTS

We would like to thank the nursing department at LSA Family Health Services for their assistance with this program evaluation. This project was made possible by the financial support of the NIH Short-term Research Training Program for Minority Students and The Break the Cycle Program.

Chapter 56

EVALUATING FISH-CONSUMPTION IN PREGNANCY

Ivorie Stanley*, MD, MPH and Susan Buchanan, MD, MPH

University of Illinois at Chicago, School of Public Health, Division of Environmental and Occupational Health Sciences, Chicago, Illinois, USA

ABSTRACT

For children particularly burdened by social and economic disadvantages, exposure to toxic substances is an important contributor to adverse health outcomes and health disparities. Maternal consumption of fish high in methylmercury during pregnancy is associated with increased risks for preterm delivery and adverse neurodevelopmental outcomes in the children. In this chapter we evaluate a single fish-consumption screening question to identify pregnant women at risk for elevated mercury levels. The question “In general, do you eat more than two fish meals per week?” was asked and a single test for total blood mercury level was obtained from pregnant women presenting to an urban hospital Labor and Delivery Triage Unit. In this limited study (n=42), participants were mainly Black (48%) and Latina (43%), and 71.4% had a median household income (estimated from zip code) below 200% of the federal poverty level. No participant had an elevated mercury level. Indeed, this population had a very low geometric mean mercury level of 0.32 µg/L (64% below the US geometric mean for women of childbearing age; from NHANES 2009-2010), indicating a likely low frequency of fish intake. In this sample population, prenatal exposure to elevated methylmercury was not an issue and the utility of this screening question was not supported. However, in these women already at risk for disparate health outcomes, the potential health benefits for brain development from omega -3 fatty acids in fish are being missed.

INTRODUCTION

For children particularly burdened by social and economic disadvantages, exposure to toxic substances in the environment is an important contributor to environmental health

* Corresponding Author's Email: istanley@uic.edu.

in 2015, with preterm births highest among non-Hispanic Black, American Indian/ Alaska Native, Native Hawaiian/Pacific Islander, and subgroups of Hispanic women. Additionally, the percent of infants born with low birth weight (weighing less than 2,500 g) saw a 1% increase, from 8.07% in 2015 to 8.17% in 2016; the highest rates of which were among non-Hispanic Blacks and Hispanic subgroups [7, 8].

In contrast, it is important to point out that fish and shellfish are excellent sources of the long-chain omega-3 fatty acids, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). These fatty acids are essential nutrients (only obtained through the diet) that confer significant neurodevelopmental benefits and may promote healthy gestational length [9]. There are other sources of short-chain omega-3 fatty acids, such as flax seed, which are less potent. As a result, the American College of Obstetricians and Gynecologists (ACOG) conferred with the US Food and Drug Administration (FDA) and the US Environmental Protection Agency (EPA), and encourages women who are or who may become pregnant or who are breastfeeding to eat at least 8 oz., up to 12 oz. (approximately 2-3 servings) of low mercury fish per week [6, 10].

Considering both factors, maternal fish consumption practices can have significant implications for children's health and development. Currently, pregnant women are not screened for fish consumption to assure adequate intake of omega-3 fatty acids and minimal mercury intake. Through the use of a simple screening question that can be incorporated into busy outpatient prenatal care, this study aims to evaluate use of a single screening question to identify pregnant women with elevated total blood mercury levels.

Among socioeconomically disadvantaged pregnant women, evaluating fish consumption practices may offer insight into dietary contributions to suboptimal neurodevelopment. By identifying pregnant women at risk for high dietary mercury exposure, we can provide additional monitoring and targeted interventions to limit potential gestational and neurotoxic effects. For those at risk for low DHA/EPA intake, we can directly promote neuro-protective dietary choices. Recognizing both high methylmercury and low DHA/EPA intake, informs opportunities to slow the gears of premature birth, poor nutrition, toxicant exposure, and neurotoxicity in order to help break the cycle of environmental health disparities (see Figure 1).

OUR STUDY

This cross-sectional study was conducted at a state hospital in Chicago, IL that serves a large proportion of minority and low socioeconomic status patients. The main study components were a brief, in-person interview and a single blood test for total mercury. Study participation was voluntary. Potential participants were eligible if: a) an adult woman (age $\geq$ 18 years), b) currently pregnant, c) able to consent to participate in the study, and d) their care required a venipuncture during the time of recruitment. Potential participants were recruited from the Labor and Delivery Triage Unit when they met study eligibility. Out of respect for the patients and the flow of care, women presenting in critical condition or in distress were not approached for recruitment. All recruitment, consent, and research was conducted by the single physician researcher and approved by the University of Illinois at Chicago Institutional Review Board.

Consent for participation in the study required a level of English language proficiency to understand the consent form and to answer the screening and demographic questions. Consent forms were available in English and all study materials were approved by the University of Illinois Institutional Review Board. Participants provided written consent to participate in the interview and allow the collection of a single blood sample.

The question “In general, do you eat more than two fish meals per week?” was asked of consenting pregnant women. Each participant was assigned an ID number, and then their medical record number, due date, date of birth, zip code, ethnicity, and response to the fish consumption question were recorded. The ID number served as a code to link the patient to their medical record number, which was kept separate from the remaining study documentation. This was necessary for the follow up required for results greater than or equal to the EPA reference dose-equivalent of 5.8 µg/L. In the event of an elevated result, a site provider would be contacted and provided the medical record number to access the patient’s contact information. The provider would notify the patient of their result by telephone.

The ID code was written on the vacutainer tube by the researcher and was the only information on each tube. A single blood sample was collected by the patients’ provider at the time they performed any other necessary venipuncture. The samples were refrigerated onsite before being shipped to the designated lab holding an ISO 9001-2000 certification and accreditation by the College of American Pathologists. All lab results were analyzed at the same lab. During the encounter, the researcher was also available to discuss low-risk fish consumption, answer questions, and provide pamphlets in English (“Eat fish, choose wisely. Protect against mercury”) or Spanish (“Advice about eating fish. What pregnant women and parents should know”) for the women and their families to keep (see Figure 2A, Figure 2B).

On research days, over the course of five months in 2017, an attempt was made by the researcher to recruit all eligible patients who presented to Labor and Delivery Triage Unit. Participants were excluded if not mentally competent to provide consent ($n = 1$). There were also 15 consented patients who met eligibility requirements but were excluded after no blood sample was collected for reasons that included: provider forgot to draw the additional tube, an inability to acquire adequate blood sample, the care plan changed and no longer required a venipuncture, or their care didn’t progress to include the venipuncture during the window of researcher availability. Approximately 22 women declined study participation, with seven women citing an unwillingness to participate in research and approximately 15 woman citing labor pain or other discomfort. There were 10 Spanish-speaking only patients who couldn’t be consented based on language. Numerous patients ($n = 50+$) were ineligible because their care plan did not include venipuncture. In total, 42 participants were successfully recruited, with data available for analysis.

Descriptive and analytical statistics were used to characterize the study population, and to evaluate the fish consumption practices and mercury level of participants by demographic factors like age, ethnicity, and income. To evaluate the utility of the screening question, sensitivity, specificity, positive predictive value, and negative predictive values were calculated. Results were also compared to national levels published by NHANES. Statistical analyses were performed using SAS Enterprise Guide 6.1 (SAS Institute Inc, Cary, NC).

Figure 2A. Informational pamphlet, English.

Source: <https://www.fda.gov/downloads/Food/ResourcesForYou/Consumers/UCM536614.pdf>.

Figure 2B. Informational pamphlet, Spanish.

The geometric mean was calculated by taking the natural logarithm of each concentration, computing the mean of those log-transformed values, and exponentiating the value to the original scale. Fifteen (35%) blood mercury levels were below the limit of detection (LOD) and assigned a value equal to the detection limit divided by the square root of two. Income level was approximated by the zip code reported by each participant at the time of the study. The incomes used for analysis were the median household incomes for a family of four, as populated from an online search of the respective zip codes. The data was from the American Community Survey 2016 5-year estimates, using comparable income statistics available from the US Census Bureau, with values in 2016 inflation-adjusted dollars [11].

FINDINGS

Table 1 shows the demographic characteristics of the 42 study participants. The mean participant age was 27 years (+ 5.6 years), with a range from 18 to 37 years old (43% were aged 18-24 years). Regarding country of ethnic origin, 48% self-identified as Black and 43% as Latina, with the remaining identifying themselves as White (7%) and Other (2%). Thirty (71.4%) of the participants had a median household income (estimated from zip code) below 200% of the federal poverty level.

Table 1. Demographic characteristics of study participants

	Total (N=42)	
Age (years)	Frequency	Percent
18-24	18	43%
25-29	7	17%
30-34	12	29%
35-39	5	12%
40+	0	0%
Mean Age (SD=)	27	(SD = 5.7)
Race/Ethnicity		
White, Non-Hispanic	3	7%
African-American	20	48%
Hispanic/Latina	18	43%
Other	1	2%
Asian/ Pacific Islander	0	0%
Trimester		
1	12	29%
2	3	7%
3	27	64%
Mean Gestational Age (weeks) (SD =)	27.2	(SD = 13.2)
Income (by zip code)		
<\$46, 435/year	30	71%
>\$46, 435/year	12	29%
Mean Income (SD=)	\$ 56,084.26	(SD = 13,849.86)

Of those who reported eating fish more than twice weekly ($n = 4$), the mean blood mercury level was $1.11 \mu\text{g/L}$ compared to a mean blood mercury level of $0.37 \mu\text{g/L}$ for those who do not ($p = 0.05$). Age was also found to be associated with mercury level; participants aged 27 years (the median participant age) or older had a mean mercury level of $0.55 \mu\text{g/L}$, compared to $0.31 \mu\text{g/L}$ in those aged 26 years or younger ($p = 0.05$). No significant difference in mercury levels were found for the remaining variables related to ethnicity, income, and trimester (see Table 2). The screening question was not found to have utility in this study population with low mercury levels. Using both the $>5.8 \mu\text{g/L}$ and $>3.5 \mu\text{g/L}$ limits, we found a sensitivity of 0.0% (95% CI: n/a), specificity 90.5% (95% CI: 76.5%, 96.9%), negative predictive value 100% (95% CI: 88.57%, 100%), and positive predictive value 0.0% (95% CI: 0%, 60.4%).

Table 2. Distribution of blood total mercury ($\mu\text{g/L}$), by select demographics

DISCUSSION

This small study of mainly young, urban, Black or Latina, low-income women looked at a single question about fish-consumption during pregnancy to assess for a possible association with mercury levels. No participants were found to have elevated total blood mercury levels, but this population had a low geometric mean mercury level of 0.32 µg/L. This compares to studies in this geographic area (the great lakes coast region) with a geometric mean of 0.78 µg/L (95% CI: 0.75, 0.82) [12] and to the national mean among non-Asian women of childbearing age of 0.58 µg/L [13]. When looking specifically at Black and Latina women of reproductive age, estimates of the geometric mean of blood mercury were 0.50 µg/L (95% CI: 0.44, 0.57) for non-Hispanic Blacks and 0.35 µg/L (95% CI: 0.30, 0.40) for Mexican Americans (NHANES 1999—2002) [14].

Given the low sample size, the statistical analyses in this study were limited. Total blood mercury level was found to be associated with whether someone typically eats fish more than twice a week. We also found that older age (i.e., age greater than or equal to the median participant age of 27 years) was associated with increased fish consumption, as seen in other studies [12, 13]. No other variables were found to have a statistically significant association with mercury levels. The screening question was not found to have utility for this study population due to the low prevalence of fish consumption and the absence of elevated blood mercury levels.

While not formally part of the research, during conversations with each participant, the researcher noted that most women (over 90%) did not eat fish regularly and were unaware of the health benefits of omega-3 fatty acids for developing babies and children. The health care professionals (to include physicians, midwives, and nurses) in the unit also expressed limited knowledge and understanding of what to communicate about fish and seafood consumption in pregnancy. The providers, participants and their families were very receptive to the educational materials; they were particularly interested to learn about types of fish to avoid and types considered recommended choices.

Consistent with other literature on women of reproductive age [10, 12], most participants reported eating fish at rates much lower than the recommended twice a week (8–12 ounces per week). As a result, the offspring from this study population may not be getting the benefits of optimal omega-3 fatty acid intake. Maternal consumption of the omega-3 fatty acids found in fish supports fetal brain and neurologic development and is associated with increased birth weight and longer gestation [9]. These are key areas where lower income and/or Black and Latina women continue to experience disparate health outcomes. By encouraging consumption of fish high in omega-3 and low in mercury, there is an opportunity to intervene and potentially improve outcomes for child health and development, and reduce health disparities.

This study has several limitations. Participants self-selected into the study, thus patients choosing to participate may be more attentive to their health and have different nutritional habits and exposures than those who did not participate. Additional bias may be introduced by participants' responses to the screening question, including inaccurate recall of fish consumption practices or the desire to provide a seemingly socially desirable response. The small sample size and study design considerably limited the strength and detail of analyses that could be performed. The inclusion of additional variables for stratification, including

varying levels and types of fish consumption and other dietary habits (including the use of omega-3 supplementation), would allow more detailed assessments of the risks.

CONCLUSION

In the face of numerous social and environmental threats to health, it is important to look for opportunities to promote health and build resiliency. By evaluating fish consumption practices, particularly for vulnerable pregnant women, there is an opportunity for neurodevelopmental health promotion. The very low rates of fish consumption among low income Black and Latina pregnant women in this study may signal suboptimal omega-3 fatty acid (DHA/EPA) intake and therefore the loss of health benefits to neurodevelopment of their offspring, potentially contributing to the achievement gap already well documented among these populations. Consuming low mercury fish at least twice a week, or ensuring comparative supplementation of omega-3 fatty acids, would likely help address some of the health disparities suffered by African American and Latino communities in the United States.

Considerations from this study may be used to guide further investigations and to target outreach to populations at risk for poorer health outcomes. Appropriate dietary choices can help limit further toxic insult and build developmental resilience, to ultimately help break the cycle of children's environmental health disparities.

Atlanta, Georgia, USA

ABSTRACT

According to the Centers for Disease Control and Prevention statistics, African American women are less likely to breastfeed compared to other racial/ethnic groups. Just over 60% of African American mothers initiate breastfeeding, with only 14% continuing to exclusively breastfeed until their infant is six months of age. Despite this persistent disparity, few studies have explored the barriers and promoters to initiating and sustaining breastfeeding specific to African American women. In this study we used a “positive deviant” model to help understand the factors that have influenced the experiences of African American mothers who have exclusively breastfeed for at least six months. Ten African American women who had given birth within the previous year were recruited through a lactation center located in the southeastern region of Atlanta, GA. Semi-structured interviews were conducted with these women regarding the initiation and sustaining of breastfeeding for six months or longer, as well as the social, cultural, environmental, and economic factors that may have acted as barriers and/or promoters to breastfeeding. Interviews were transcribed and general qualitative data analyses using MaxQDA utilizing intra-and inter-rater reliability techniques were carried out. Results: The majority of the participants described the following as positive factors:

* Corresponding Author's Email: danielle.dimacali@emory.edu.

† Corresponding Author's Email: jeannie.rodriguez@emory.edu.

supportive family, workplace autonomy, and support groups. Barriers included: long commute, work hours, stressful environments and difficulty latching. Conclusion: This group of African American women are positive deviants and key informants in identifying barriers and promoters of exclusively breastfeeding for at least six months. Our findings will help generate hypotheses on community and culturally tailored interventions to encourage more African American mothers to initiate and sustain breastfeeding.

INTRODUCTION

Breastfeeding is regarded as the optimal form of infant feeding because of the many benefits it provides to infant and child health and development [1]. The American Academy of Pediatrics (AAP) policy on breastfeeding recommends exclusive breastfeeding for six months, followed by continued breastfeeding as complementary foods are introduced, with continuation of breastfeeding for one year or longer as mutually desired by mother and infant [1].

Breast milk affords protection against many health problems in infancy, such as obesity, diabetes, infections including necrotizing enterocolitis, and allergic disease [2]. Additionally, Bar et al. reviewed the long-term neurodevelopmental benefits of breastfeeding and found that children who breastfeed for longer than six months have better cognitive outcomes, including a lower risk of developing attention-deficit/hyperactivity disorder, and higher intelligence quotient [3].

Additionally, breastfeeding benefits the infant's immune system through contributing to the seeding of the microbiome by introducing new microbial communities and stimulating the maturation of the neonatal gut microbiome [4]. The microbiome matures in parallel with the infant's immune system, setting up the framework for the adult immune system and microbiome, by developing regulatory T-cell populations [5-7]. Bacteria located in both colostrum and mature milk can stimulate the anti-inflammatory response, helping to reduce the risk of developing a broad range of inflammatory diseases and immune-mediated pathologies, such as asthma, inflammatory bowel disease and atopic dermatitis [4, 8]. According to Houghteling, the nature of infant environmental exposures, acting through the microbiome, affects the likelihood of developing other diseases such as obesity and food allergies [4]. Hence, the best way to promote and maintain a healthy neonatal microbiome is through exclusive breastfeeding [6].

Health concerns for children such as asthma, obesity, hypertension, diabetes, and neurodevelopmental disorders are often caused or exacerbated by socioeconomic and ecological factors. Children who are breastfed for longer periods have lower infectious morbidity and mortality and higher intelligence quotient (IQ), than do those who are breastfed for shorter periods, or not breastfed [9]. This inequality persists until later in life [10]. Through increasing the breastfeeding initiation and sustaining rates, we can help to break the cycle of health and developmental disparities in children that lead to poor physical health in adulthood.

According to the Centers for Disease Control and Prevention, African American women have a breastfeeding initiation rate of 64.3% compared to 81.5% of white women [11]. Furthermore, African American mothers exclusively breastfed for 6 months at a rate of 14%

compared to 22.5% of white women. Hence, African American mothers and their babies are at higher risk for poorer health and developmental outcomes. Little is known about what promotes and helps to maintain exclusive breastfeeding for the 14% of African American mothers who are successfully breastfeeding up to six months.

Figure 1. Cycle of environmental health disparities.

Despite the lower rates that exist with African American mothers' breastfeeding initiation and sustaining practices there is a lot to learn from women who have been successful. Through their narrative we are able to identify and highlight positive promoters of breastfeeding and learn about the challenges African American mothers overcome to reach their breastfeeding goals. Rather than focus on the black-white disparity in research as it reinforces a deficit model, we sought to humanize the gaps in research through narratives and input from African American mothers who have successfully breastfed [12]. We chose to validate the significant improvements of African American breastfeeding rates through the behaviors of positive deviants.

African American women who do breastfeed may be considered positive deviants. A positive deviant approach examines behavior that deviates from the norm to produce favorable outcomes. According to a pioneer on the study of positive deviance, this approach allows a participatory approach to identify solutions to community problems within the community [13]. In every community, there are exemplary individuals who display unconventional and uncommon practices and behaviors that enable them to find creative solutions compared to their counterparts who have access to the same resources [14, 15]. Through identifying individuals with better outcomes than their peers and analyzing their behaviors, other members of the communities could be encouraged to adopt the behaviors as an effective method to produce sustainable and locally sourced change [16]. Rather than

identifying a problem and creating a solution, we seek to identify the solution and work backwards to solve the problem [17]. In healthcare, the positive deviance approach is successful through presuming that the knowledge about ‘what works’ exists in identified communities [18].

In order to bring about sustainable and applicable improvements in breastfeeding rates among African American women, it is essential to ask those mothers who have exclusively breastfed to share their insight on how they overcame barriers and accomplished their desired goals. The aim of this study was to understand the lived experience of African American women who have exclusively breastfed their infants through 6 months of age. This research design was inspired by a 2017 study by Gross titled “*Long-term breastfeeding African American mothers: A positive deviance inquiry of women, infant, and children (WIC) participants*,” in which she conducted semi-structured, in-depth interviews from exclusively breastfeeding mothers from the Women, Infant, and Children (WIC) programs in three local health districts in Georgia to gain insight on their breastfeeding experiences [12, 19]. WIC is a federally funded health and nutrition program for pregnant, breastfeeding, and postpartum women whose household income is under the federal poverty line [12]. For breastfeeding mothers, WIC offers lactation counselors to provide information and support breastfeeding.

We sought to develop a similar study with interviews from African American mothers who utilize lactation counselors outside the realm of WIC. We focused on the lived experiences of exclusively breastfeeding African American women recruited from a community partnership with Breastfeed Atlanta, a network of lactation centers serving the metropolitan Atlanta area. Breastfeed Atlanta is a private lactation center in Atlanta, which employs trained professional lactation consultants who take a thorough breastfeeding history, assist with feeding, and provide evidenced-based information for a customized breastfeeding care plan to individualize care and education to increase breastfeeding rates [20]. Breastfeed Atlanta accepts some insurance plans but also allows clients to pay out of pocket for lactation services at Breastfeed Atlanta’s office or in the client’s home. These services can range from \$75 to \$220 per visit [20]. Thus, the network of African American mothers recruited from this lactation center could either have insurance coverage or afford out of pocket expenses.

Through examining factors that served as barriers and promoters of breastfeeding within the African American community, we sought to generate hypotheses on community and culturally tailored interventions to encourage African American mothers to initiate and sustain breastfeeding. The results of this study will be used to build future interventions to address barriers to breastfeeding among African American women and support the creation of community tailored breastfeeding education and interventions in lactation centers, hospitals, workplaces, and society to break the cycle of infant health disparities.

OUR STUDY

Ten African American mothers who had exclusively breastfed for at least six months were given the opportunity to reflect on their breastfeeding experience identifying factors that helped them to breastfeed and factors that may have been barriers; such as cultural expectations, social support, economic conditions, education and environmental factors.

The ten semi-structured interviews were conducted by three researchers (DD, CM, JF). The interviews were conducted in February and March 2018 at the mother's choice of time and location ranging from homes, workplaces, the lactation center, and coffee shops. The geographic context for this study was within the metropolitan Atlanta area. In collaboration with the lead Lactation Consultant of Breastfeed Atlanta who did the recruiting using a

recruitment flier and capitalizing on Atlanta Lactation Center's ListServ and Facebook contacts. To be eligible for interviews, women were required to self-identify as African American adult women, 18 years or older, be able to read and understand English, be able to consent for study participation, and have breastfed their infant for at least six months. Furthermore, the breastfeeding experience should have been initiated no longer than 12 months prior to the present interview and the infant that was breastfed was a singleton birth and was appropriate for gestational age in size at birth. Exclusion criteria were infants born at less than 37 weeks gestation, spent more than one week in the neonatal intensive care unit after birth, or had a medical condition such as gastroesophageal reflux disease or cerebral palsy, that could make breastfeeding difficult.

There were 32 women who expressed interest and were screened via telephone. Ten mothers did not meet the inclusion criteria, twelve were unable to schedule interviews, and ultimately ten interviews were conducted. Informed consent was obtained, and demographic questions were asked, including age, ethnicity, gender, marital status, educational level, employment status, household income, number of children, and number of children exclusively breastfed for six months. Demographic forms were based on the CDC Questionnaires: Breastfeeding and Infant Feeding Practices [21]. During the 1-1.5-hour semi-structured interviews we asked questions about initiating and sustaining breastfeeding, social, cultural, educational, environmental, and economic factors (see figure 3). The interviews were recorded and given an interview code to ensure participant confidentiality, pseudonyms were created using the participant initials and number of the participant. Participants received a \$10 gift card to Amazon or Target as compensation for their time.

The content of the tape-recorded interview was fully transcribed by their respective interviewers. Interrater reliability was checked with one person having experience and training conducting qualitative interviews. The interviews were then analyzed using maxQDA with training from a trained qualitative faculty researcher, HB. Codes were generated by topics that mimicked the interview guide: initiating, sustaining, education, and environmental factors.

FINDINGS

There were ten breastfeeding mothers interviewed. The participants self-identified as female (90%) and (10%) as gender non-binary, between the ages of 30-35 (50%), were married (80%), academically had a Bachelor's degree or higher (90%) and worked full time (70%), with a median income of between \$60,000-\$90,000. All participants (100%) shared that they both breastfed and pumped. The demographic data is seen in Table 1. Key results from the major areas on the questionnaire explore promoters and barriers regarding: initiating breastfeeding, sustaining breastfeeding, social support, educational resources, and environmental impacts that affect breastfeeding (see Table 2).

Table 2. Interview guide

Initiation	1) I want you to think back to your pregnancy. Please describe what motivated you to breastfeed when you were pregnant. 2) Now I want you to think back to when you gave birth to your baby. Please describe your experience initiating breastfeeding after birth. 3) Now think back to the first few weeks after you had your baby. What was your breastfeeding experience like during this time?
Sustaining	1) What were your initial goals for breastfeeding, meaning how long did you plan to breastfeed for? 2) Please describe what helped you continue breastfeeding for 6 months or longer. 3) In as much detail as possible, please describe and compare your very last experience breastfeeding as compared to your first breastfeeding experience. 4) What were some barriers that you had to overcome in order to sustain your breastfeeding goals? 5) How did you overcome these barriers?
Social/Cultural	1) What impact do you think your culture had on your breastfeeding experience? 2) Was your family supportive of your decision to breastfeed? How so? 3) Was your work supportive of your decision to breastfeed? How so? 4) Did you have childcare arrangements? 5) Who were your role models or support people while you were breastfeeding? 6) What role do you think the media plays in people's decision to breastfeed?
Education	1) To your understanding, what benefits does breastfeeding give the baby? 2) How about to yourself (mother), and/or community? 3) Did you have access to breastfeeding education? 4) What prompted your decision to come to the Atlanta Lactation Center? 5) How was your relationship with your counselor at the "Atlanta Lactation Center"?
Environmental	1) To your understanding, what environmental factors (e.g., smoking, drinking, medications, illicit drugs, cosmetics, birth control) influence breastfeeding? 2) Do you know of any other environmental factors that influence breastfeeding that maybe out of your control (e.g., stress, unemployment, inadequate safety, lack of access to education, air pollution, water access)? 3) Did the environment you were in (work/school/home) have any affect on your breastfeeding? 4) I want you to now imagine your ideal environment for breastfeeding. What would that look like?
Economic	1) Can you talk a little about the expenses associated with breastfeeding, including coming to Atlanta Lactation for professional support?
Final Questions	1) I want to better understand the breastfeeding experiences of African American mothers. Is there anything that I missed? Is there anything else that you would like to share? 2) If you had the chance to give advice on how to help African American mothers to breastfeed, what advice would you give?

Initiating

Initiating, or deciding to breastfeed within the first hour after birth, is a major component to the start of the breastfeeding experience to ensure that the infant receives colostrum, or "first milk" which is rich in protective factors [22]. The first theme to emerge was regarding initiation of breastfeeding. In this sample, all mothers gave birth at a hospital and first initiated breastfeeding in a hospital setting.

Motivation to Breastfeed

When asked about motivation to breastfeed, 80% of mothers stated that they were motivated to breastfeed because they knew it was inherently a healthier option. Of those who said it was the healthier option, 25% described breastfeeding as a ‘natural’ thing to do.

“I just knew it was healthiest and I just had read research on how it helps with the health of your gut and how that kind of leads to so many health benefits and there's still research going on, but basically, I just want it to set my baby up with the best start possible now” -JF#1

“It seemed like that was the natural thing to do. It was my first option I haven’t even thought of the formula option.” -DD#3

30% of mothers interviewed stated that the fact that breastfeeding was free and was a significant motivator for them initially.

“The health benefits, and I'm very cheap, so I should add that that's a huge motivator for me at all times. There's just a cost benefit to breastfeeding as well. I mean, it's insane how much formula is while [breastmilk] you could just produce it and it's free.” -JF#3

30% of mothers were initially allured by skin to skin and the bonding aspect of breastfeeding.

“It's a moment or an opportunity for bonding. You have those, I think they say, or endorphins or whatnot that's being produced. So it just feels, I've already said it, but super satisfying, right. Um, and then you get those kind of quiet moments with your child, so you're just kind of able to be in the moment and absorb what's happening.” -DD#3

This initial foundational knowledge of the benefits of breastfeeding could be seen as motivators to mothers to initiate breastfeeding.

Goal Setting

A major recurring motif was goal setting prenatally, 80% of mothers had a goal of breastfeeding for one year, with 50% of the mothers quoting American Academy of Pediatrics (AAP) recommendations they received from AAP’s book “Caring for your baby” or from their pediatrician.

“I knew that I wanted to do it at least for the first year. That was my personal goal, just because I knew that based on research, the first year even up to two years is really beneficial for baby. So that was my goal, but I was flexible with myself and knew that that may or may not change when I went back to work. I actually made it past that. So I would say just putting the emphasis on helping before delivery and then also in the hospital” -DD#2

Furthermore, one mother cited that her initial goal was only to breastfeed for three months which correlated with her maternity leave. However, she found her breastfeeding experience getting easier and less cumbersome over time.

“My initial goal was three months and while I was on maternity leave to see how we can do this and take it from there. Then I got to 3 months and was like man 3 months came kind of fast and then I was like let’s try to 6 months.” -DD#3

While actively making the decision to breastfeed helped establish a mindset to breastfeed, however, upon initiation and their first breastfeeding experience, 60% mothers described difficulties they encountered when initially breastfeeding.

Sustaining

In order to sustain breastfeeding many mother stated that having determination was a positive promoter. Of the mothers interviewed, 50% talked about having determination to reach their goals.

“Sheer perseverance, partially being stubborn.” -JF#2

“Just prayer and determination. I mean I just set a goal and I just, I’m just keeping with it. There are times where my supply goes up and down and I recently had to travel for a week and pumped milk for that, but it’s just through consistency and discipline. I believe you can do it.” -JF#1

“It’s that determination from friends and family and support groups.” -DD#3

Difficulty Latching

An initial barrier encountered described by 60% of the mothers was difficulty latching. Of those who had difficulty latching, 50% said they found it painful to nurse which escalated into stress for the mothers, who became concerned that their babies lacked adequate nutrition.

“I think she had a shallow latch, which really made it excruciatingly painful to nurse” -CM#1

“And so, every time to try to make her latch was kind of really stressful for me because the way that it was suggested by the doctor that we saw, the pediatrician was like ‘push her head into the breast’. And then it was, it just looks so stressful for both of us. She’s so tiny and she was six pounds 15 ounces and then she was straining and crying and all that stuff.” -DD#4

90% mothers described methods to overcome these initial barriers, such as utilizing breastfeeding equipment and seeking outside help initially from a lactation consultant.

“I ended up using an SNS [Supplemental Nursing System] to put him back at the breast to try to get him to latch because there got to be a point where he wouldn’t latch at all. Christy evaluated his latch, which was horrible, so he really wasn’t really getting anything. He might’ve been getting colostrum in the hospital, but slowly but surely it just wasn’t happening.” -JF#2

Other barrier mothers in this study had to overcome included breastfeeding pain due to cracked and sore nipples, low milk supply production, time management, birth trauma and getting used to breastfeeding in public. Although barriers presented themselves during the

initiation phase, these mothers overcame them and were able to sustain breastfeeding for six months or longer.

Social Support

70% of the mothers interviewed were married and a 86% of those mothers who were married described having a supportive partner.

“He was very supportive. He was kind and encouraging me because we went to a hospital tour at Dekalb Medical, they have a breastfeeding kind-of segment because they actually have a lactation consultant do the tour so that she can kind of plug breastfeeding in there. So, he was able to hear like the importance of breast milk on his own and he knew it from before and he had always been supportive before but just to have a lactation consultant speaking to the both of us and telling us the importance of the nutrients, so he was supportive” -CM#1

One mother described how at first her partner was reluctant about breastfeeding, in particular in public, but how his views have changed over time.

“And the look on my husband's face was like, oh, like I think he could have freaked out, but he didn't want to freak out in front of everybody because nobody else was freaking out. And he slowly but surely got used to it and now he'll say ‘I can't believe the stigma of people!’” -JF#2

Another mother described how breastfeeding not only helped her bond with her baby, but it helped her husband bond with their baby as well.

“I think exclusively pumping gave me some flexibility in actually helped her get very close with her dad. She's super close with him, but we split the tasks after the two weeks when she stopped latching where it wasn't all about me. And he would feed her her bottle half the time too. So she has a really strong attachment to him as well, so I do think that was good about exclusively pumping.” -DD#4

For partners that were not described as supportive, barriers to breastfeeding included feeling like bottle feeding was more convenient.

“My husband, we're still working on him. He's cool with it and he understands that this is the most healthy option but he doesn't feel like it has to be the only option either. He's more of a convenience thing. Uh we got to stop for 30 minutes because she needs to breastfeed, why can't you just give her a bottle, or you know” -DD#3

Another barrier encountered was the stigma of breastfeeding in public and how it subsequently makes husbands uncomfortable. This particular mother described how she overcame that barrier.

“My husband's not comfortable with me not covering. So if I had it my way I would just do like the 2 shirt method. So if I nurse in public it's either in the car, in the backseat, my windows tinted or I try to find a room that no one's in, i usually try to do that at church or kind of struggled with the cover” -CM#1

Scheduling and Preparation

Of the 90% full time working mothers, 55% described how they faced barriers with scheduling and how they had to had to schedule and prepare how to pump while at work which in turn affects their production.

“The other challenge is just in the industry that I was in, it was just hard at times to pull away to go do that. My work schedule, the amount of times that you're pumping affects your ability to produce it. So that went down for me once I started working during the work day and then you get home, you're tired and so that negatively affect my production for sure.” -JF#3

Although barriers were faced, promoters discovered were active planning and preparation for optimal time management.

“So it just took a lot of planning and preparation, make sure that I had enough water and snacks because I get really thirsty and hungry when I'm pumping and nursing.” -DD#2

“I would pump when I got to work. I would pump when I got up at like six and that was hard too because I do mornings with her so then when I got to work I would pump before class and then right after class I would come, then I would hold office hours then a couple of pumps later on” -DD#4

Furthermore, of the full-time working mothers, 22% described how a long commute to work itself that served as a barrier. The two mothers described driving an hour to and from work and how they had to figure out how to pump on their nursing schedule.

“I traveled for work. I'm on the road every day. Sometimes that entails staying overnight. So having to be prepared whether that was with a cooler planning out my route so that, you know, I had time built in to stop” -DD#2

“The biggest barrier is the fact that I work full time. I have to go back to work right before her 12 weeks, but the biggest challenge that I have to pump in order to send bottles to daycare and that's really hard to get that time in. I talked to a lot of people and went to several lactation support groups here in the city and just talked to other moms and getting tips on how to make it convenient and getting a manual pump or getting the adapter that allows you to pump in the car while driving.” -DD#3

Improvements over Time

Additionally, 50% of mothers stated they were motivated because they saw marked improvements in the breastfeeding relationship over time.

“I just know so much more, I know the cues, it doesn't hurt anymore. She's a lot faster now, at the beginning it was like four-five minutes at a time and an hour and she used to fall asleep in the beginning” -DD#3

“I would say just the, probably the confidence that I gained those first few weeks helped me to realize that it was actually very easy for me.” -DD#2

Education

A major source of support for many of the participants included lactation consultants. 90% of the mothers had prior knowledge of the role of lactation consultants and knew to reach out for their help when encountering barriers.

The majority of our participants (70%) took a breastfeeding class prenatally and stated that it helped them to feel more prepared and had an idea of how to latch the baby. Of those that took a breastfeeding class, 2 out of the 7 women stated that in theory they knew what to do after taking a class but felt that they needed more support to overcome barriers:

“I had gone to a breastfeeding class at the same hospital I delivered but it was like a theory. Afterwards, I was in pain and healing and extremely tired even though I did have my mom there.” - DD#3

90% of the mothers also started receiving their education through online support groups like Facebook and reading books such as “The big letdown” and “What to expect when you're expecting.”

Knowing Your Rights

This year, 2018, Utah and Idaho enacted laws making breastfeeding in public a legal right in all 50 states plus the District of Columbia, Puerto Rico and the Virgin Islands. A few mothers mentioned the importance of knowing breastfeeding rights in order to advocate for themselves in the workplace. While the majority of our participants had supportive work environments they encountered other women on their online support groups for which this was a huge barrier.

“Learning about the state regulations that protect your right to breastfeed at work, like having lactation areas and having an area designated for you and have to make a reasonable attempt to allow you space and time to pump. Learning all of those helped me to advocate for myself was important and learn how to talk to my CEO.” -DD#4

Health Benefits for Mother, Baby, Community

70% of the mothers mentioned mother–infant bonding as a benefit of breastfeeding to mothers, babies and the community. For the breastfeeding benefit to babies the most common responses included overall healthier babies, brain development, complete nutrition, and reduction of SIDS. One mother stated that the reduction of SIDS was the strongest motivating factor for her decision to breastfeed her second baby.

“So, I think just overall healthier babies and healthy parent-infant relationships, and maybe more confident babies.” - CM#1

“I think it helps the community because it sets a healthy example for mom and baby. I think it helps baby be happier. I think it helps baby be healthier.” - DD#2

“Health benefits for the baby, it reduces SIDS. That really turned me on because that’s really scary part when you first have kids. The health benefits.” -CM#3

Environmental

We asked mothers what environmental factors served as barriers to their breastfeeding experience, 40% cited stress as a barrier to breastfeeding.

“I would say stress, because I am a single mom... stressing sometimes does sometimes affect your milk supply, so I can empathize with ones who are financially struggling having or having housing or shelter struggles, and how that stress can affect your decision.” JF#1

“Stress will kill your breastfeeding journey.” CM#3

“If you have at home stress, if you're not a stable living situation. I definitely understand how I'm breastfeeding can be very difficult.” DD#2

We concluded our interviews with asking this study group to give advice on how to help African American mothers to breastfeed they stated these pearls of wisdom:

“Have a support system of other African American mothers”
 “Realize why you want to do it and push beyond previous generations assumptions”
 “Find people that are going through what you’re going through”
 “Know that you are all they [babies] need”
 “Reward yourself. If I make it to 6 months, what am I going to do for myself?”
 “The benefits outweigh the difficulty in the beginning.”
 “Support and encourage each other. Be willing to give someone a demonstration.”
 “Know that you’re doing what’s best for her.”

Table 3. Benefits of breastfeeding

Benefits for babies	Benefits for mother	Benefits for the community
Mother-Infant Bonding	Mother-Infant Bonding	Healthier communities
Overall healthier babies: • Brain development • Complete nutrition • Decrease SIDS	Saves time	Cost savings for healthcare system
Changes specifically to babies needs	Saves money	Environmental benefits
	Cancer reduction	
	Losing weight	

DISCUSSION

Breastfeeding has been shown to benefit mothers, babies, and the overall community. The rates of breastfeeding initiation and breastfeeding exclusively for 6 months or more are lower among African American women (14%) compared to white women (22.5%). In this study we conducted qualitative semi-structured interviews with ten African American women who had exclusively breastfed for at least six months, each with their own personal narratives, promoters, and barriers they faced. Each mother expressed interest in trying to better

understand why the breastfeeding initiating and sustaining rates among African American women were significantly lower. We hoped to understand the factors that have influenced the experiences of African American women that have exclusively breastfed their infant through six months of age. We chose to use the ‘positive deviants’ model by identifying women who had successfully breastfed for 6 months or more, and learn about the factors that have been promoters and barriers in their breastfeeding experience.

In Gross’ study, her positive deviants were African American mothers from the WIC programs, which primarily serve mothers with household incomes below the federal poverty line [12]. In this study, the positive deviants were African American mothers recruited through Breastfeed Atlanta, a metropolitan lactation center, who have higher median income to be able to afford lactation services. In our sample, all ten mothers had a median income between \$60,000-\$90,000 and were educated, informed, affluent, motivated, employed and had supportive families and social networks. The mothers from Breastfeed Atlanta are in accordance with those mothers in the Gross study from WIC who sought African American lactation support personnel and African American breastfeeding support groups [12]. Despite having higher income levels, this study of mothers also emphasized the importance of having a community of other African American mothers to support and encourage each other. Thus, the desire to have support within the African American community transcends poverty lines and socioeconomic status.

Furthermore, the breastfeeding mothers in this study also offered insight for working African American mothers above poverty level who are navigating the unique workplace challenges related to breastfeeding. For example, 55% of the mothers encountered barriers around scheduling pumping time at work in order to maintain their milk supply. Ultimately, most of the advice the mothers provided were free and accessible and could be utilized by other African American women as well as by online educational resources and support groups.

Learning about the promoters and barriers for women that have successfully breastfed for up to 6 months, offers valuable insight on social, cultural, economic and environmental factors that influence breastfeeding rates among African American women. The promoters identified were: prenatal goal setting, cost savings, educational resources, knowing your rights, Facebook groups, and knowing multisystem health benefits for the baby, mothers, and community. The women in this study felt that their determination and the support of lactation consultants, online support groups and friends and family acted as positive promoters in reaching their breastfeeding goals. These mothers showed a passion and ardor to reach their goals, especially through prenatal goal setting and partners who support their goals. Thus, the internal determination and steadfastness to commit to goals of these mothers ultimately led to their success.

This study also revealed barriers that the women had to overcome such as: difficulty latching, stigma, work schedules, commutes, and stressful environments. An overwhelming 60% of mothers reported difficulty latching as a major barrier to breastfeeding exclusively. The mothers stated were able to overcome this barrier because they were motivated by improvements in the breastfeeding relationship with their infants after gaining the knowledge, the experience and the skill to persevere. In this context, lactation consultants were crucial in educating women on breastfeeding frequency, latching, increasing their milk supply and assuring mothers that their babies were getting enough milk. Furthermore, community groups such as online support groups on Facebook created a sense of community and gave

representation and role models of other African American women breastfeeding. Therefore, proper knowledge of how to improve latching and when to seek out additional help is important in educating and affirming African American women that they are capable, and it is possible.

Another barrier encountered was the stigma regarding breastfeeding, including how it inconveniences their partner or makes them uncomfortable, however, emotional and social support was crucial for sustain breastfeeding longer than six months. Ultimately 70% of the mothers described having supportive partners whether it was initially, because of early education efforts, or over time throughout the breastfeeding experience. These mothers highlighted the importance of including the partner in early education efforts about the multisystem health benefits for the baby, mothers, and community, allowing the partner to build a bonding relationship with the baby, and breastfeeding using blankets and covers.

Additionally, 90% of the full-time working mothers described scheduling and lengthy commutes as barriers to breastfeeding. The mothers described combatting this with active planning and preparation including food, water pumping supplies and chargers, and portable refrigeration systems. Furthermore, carving out the time around the work schedule was difficult but a few mothers mentioned the importance of knowing breastfeeding federal laws in order to advocate for themselves in the workplace. Thus, through a knowledge base of the rights, and with advanced scheduling, breastfeeding can be possible despite a full-time schedule and lengthy commute. All the mothers in this study reported pumping in their breastfeeding journeys.

Based on the barriers and promoters identified in the study, our recommended breastfeeding community interventions for African-American mothers include helping new mothers establish breastfeeding goals prenatally and equipping them with evidence-based education. Furthermore, it is important to encourage providers and hospitals to make referrals to lactation consultants and incorporate lactation education for expectant mothers and families. The mothers in this study felt more prepared in initiating breastfeeding after receiving breastfeeding education. Additionally, women should receive education on their breastfeeding rights and other environmental factors that influence breastfeeding and the health of our communities overall. This study group received their education about breastfeeding through their healthcare providers, nurses, online support groups, breastfeeding class and lactation consultants. Breastfeeding education is readily available and free for mothers who have internet access and know how to navigate resources online. Access to lactation consultants was integral in helping the mothers overcome physical and emotional barriers to breastfeeding.

Some of the mothers in this study benefited from insurance coverage for lactation consultants and breastfeeding pumps. Hence, having health insurance coverage for lactation consultants and for breastfeeding supplies helps to alleviate monetary constraints and promotes the sustaining of breastfeeding.

The mothers we interviewed had relatively high autonomy in their workplace and most were able to breastfeed during work hours. Regardless of socioeconomic status, African American mothers should be equipped with knowledge of the laws surrounding adequate breastfeeding and accommodations in the workplace and tools on how to advocate for themselves. For example, in the state of Georgia, Ga. Code An. § 34-1-6 states “An employer may provide reasonable unpaid break time each day to an employee who needs to express breast milk for her infant child. The employer may make reasonable efforts to provide a room

or other location (in close proximity to the work area), other than a toilet stall, where the employee can express her milk in privacy.” Thus, break times could be used to schedule adequate pumping schedules to not affect milk supply.

It is important for healthcare providers to educate African American women on their resources and services available to them, whether it be through their insurance coverage with lactation support services or community resources available. Lactation consultants were integral in helping mothers overcome physical and emotional barriers to breastfeeding. Ultimately, it is crucial to build community by linking African-American women with other African-American mothers who practice exclusive breastfeeding. Equipping mother prenatally with resources in their local community or on an online forum such as the Facebook group “Black Moms Do Breastfeed” [23]. Fundamentally, 100% mothers found reassurance that they were doing what they thought was best for the baby. It is important as health care professionals and society to provide affirmations and reassure mothers they are capable of adequately feeding their baby solely through breast milk.

The sample in this study was from a highly selective population that may not reflect the general African American population. The majority of mothers interviewed in this study were married, with higher levels of education, and above the poverty line which revealed promoters and barriers that may not be relatable to other African American mothers who lack similar resources. Another limitation was mother’s self-reporting on exclusivity of breastfeeding. Although our inclusion criteria required exclusively breastfeeding for six months, 80% of mothers divulged that they supplemented with formula for short periods due to overcome latching and milk supply difficulties. During the inclusion screening these mothers self-identified as exclusively breastfeeding (Figure 2). During our phone screening, we relied on self-reporting of the mother to deem themselves exclusively breastfeeding for 6 months. Therefore, a major limitation in this study was failing to include any type of “formula supplementation” as an exclusion criterion.

CONCLUSION

Although the Centers for Disease Control and Prevention reports that African American mothers do not initiate or sustain breastfeeding at the same rate as white mothers, there are African American mothers who do breastfeed and from whom lessons can be learned that can encourage other African-American mothers to breastfeed successfully and overcome this disparity in breastfeeding practices. The insight gained in this study from the positive deviants can be amplified to address this public health issue of racial disparities in breastfeeding. Health care professionals serving diverse populations should actively and encourage a supportive culture surrounding breastfeeding through the establishment of prenatal breastfeeding goals, educational support for healthcare providers and mothers, African American community groups, and providing affirmations during the breastfeeding experience particularly for all African American mothers. Thus, the lessons from the breastfeeding African American mothers in this study can help break the cycle of children’s environmental health disparities by providing insight on barriers African American women face regardless of income level or access to services, and offers valuable promoters that can be utilized by other African American mothers to overcome breastfeeding difficulties.

ACKNOWLEDGMENTS

This project was conducted through Break the Cycle of Environmental Health Disparities: Reducing Children's Environmental Health Disparities and Promoting Health Equity for all Children. We would like to thank the SE PEHSU. We would like to thank Breastfeed Atlanta and the owner Christy Courissey for her support in recruitment efforts and enthusiasm for addressing breastfeeding racial disparities. We would like to thank Dr. Tyra Gross from Xavier University for being a liaison, an inspiration, and a great mentor.

ABSTRACT

In this chapter we aimed to examine associations between maternal childhood abuse and maltreatment, early parenting behaviors, and infant neurodevelopment among African American mother-infant dyads. Maternal adverse childhood experiences (ACEs) were assessed during pregnancy using the Childhood Trauma Questionnaire, and early parenting behaviors were assessed by coding videotaped observations using an adapted version of The Three-Bag Assessment when infants were 3-months of age. Infant neurodevelopment was assessed using the cognitive and motor subscales of the Bayley Scales of Infant and Toddler Development. At the time of this analysis, 59 mother-infant dyads had ACEs exposure, early parenting, and infant neurodevelopment data available from the infant 3-month assessment. Preliminary findings suggest no main effects of maternal adversity on infant neurodevelopment and indicated no significant interaction effects between maternal adversity and early parenting behaviors, although this study may have been underpowered to detect a small effect given the sample size available. It is still possible that these factors predict the rate of neurodevelopment beyond the first three months of life, which will be examined using growth curve analyses in future studies. The overall goal of this ongoing research is to explore parenting behaviors as a key point

of intervention that may reduce the intergenerational impact of ACEs on child neurodevelopmental outcomes, thereby breaking the cycle of risk.

INTRODUCTION

Exposure to adverse childhood experiences (ACEs), such as poverty, abuse, or neglect, represents one of the most prevalent and detrimental risk factors for abnormal biological, psychological, and behavioral sequelae [1]. Over the years, empirical studies have suggested that childhood adversity is associated with dysfunction within the neuroendocrine system [2], increased risk of psychopathology [3], and later perpetration of violence [4]. Recent studies have also indicated that the effects of ACEs have the potential to cross generational lines and impact offspring's socio-emotional and developmental outcomes [4]. Much of the research on the long-term outcomes associated with ACEs has been guided by the Life Course Model, which considers how chronological age, relationships, and social factors shape people's lives from birth to death [5]. There is overwhelming evidence that ACEs can impact later outcomes well into adulthood across behavioral, social, and cognitive domains [6, 7], and studying ACEs from a life course perspective acknowledges that there is a unique relationship between time, experience, and human development. While individual trajectories vary, patterns can be predicted based on environmental exposures and experiences.

For example, evidence continues to amass that individuals who reside in lower socioeconomic status (SES) communities are disproportionately exposed to early life adversity [8]. Low SES has been cited as a risk factor for child abuse perpetration among caregivers [9], and children who live in low SES communities are also more likely to be exposed to violence, neglect, various forms of abuse, and caregiver substance use or serious mental illness [9]. Further, researchers examining the long-term impact of childhood abuse have suggested that early childhood victimization affects later economic stability [10-12]. Zielinski [10], for example, found victims of child maltreatment to be at an increased risk of financial and employment-related difficulties in adulthood. Poverty thus serves as both a consequence of and a risk factor for other ACEs and may play an important role in the intergenerational transmission of adversity (see Figure 1).

Importantly, children of mothers with a history of childhood adversity, even in the absence of ACEs themselves, are at increased risk of internalizing and externalizing problems, such as anxiety, emotion dysregulation, aggression, delinquency, and overall worse adjustment over time [13, 14]. Maternal ACEs have been linked to child emotional development and behavioral problems at ages 4 and 7 years [13] and disruptive behavior during adolescence [15]. The impact of maternal ACEs on child cognitive and motor development in infancy is less well studied and is the focus of the current investigation.

Poor parenting practices may be one mechanism by which maternal ACEs negatively impact infant neurodevelopmental outcomes. Empirical studies have demonstrated that maternal childhood exposure to violence, neglect, emotional maltreatment, and sexual abuse are significantly associated with mothers' observed hostility toward their children and concerns related to their parenting competence [16]. Maternal ACEs have also been linked to decreased maternal responsiveness, sensitivity, and positive affect, which reflect her ability to have a prompt and appropriate response to her child's needs [17]. Maternal childhood adversity may therefore impair her ability to form secure attachments with her child [18],

which aligns with Bowlby's attachment theory [19]. This theory suggests individuals develop an "internal working model" during infancy that serves as the basis of their worldview. The infant signals its needs for care, and differences in the quality of attachment are due to the caregiver's responsiveness and sensitivity to the child's needs. From this interaction, infants then form their basic expectations about the environment. Abuse, inconsistency, or rejection from a primary caregiver can diminish the quality of the bond, thereby negatively impacting the child's developmental outcomes.

Figure 1. Factors that maintain the cycle of disadvantage and disparities.

On the other hand, positive parenting might ameliorate the potential negative impact of maternal ACEs on child outcomes. Warm, supportive, and stable relationships have consistently been cited as protective factors across a number of studies [20] and are thought to be critical to normal child development. Indeed, positive parenting strategies are believed to promote child independence, facilitate the achievement of other developmental outcomes, and are frequently linked to increased child cognitive performance [21]. For example, positive mother-child interactions have been linked to higher scores on infant mental development indices at 12-weeks [22], and child cognitive development has been described as a function of maternal responsiveness [23]. Responsiveness often includes providing appropriate levels of stimulation in ways that support children's learning [23]. Additionally, it has been theorized that maternal responsiveness affects mother-infant attachment, which consequently determines the degree to which the infant feels secure enough to explore his or her surroundings [23]. Positive parenting behaviors are therefore beneficial for young children's development of emotional security, social competency, and independence. Previous studies have primarily focused on the impact of negative parenting practices that are associated with maternal ACEs. However, maternal ACEs and poor parenting do not always go hand in hand. One of the aims of the current study is to examine positive parenting as a potential moderator of the relationship between maternal ACEs and infant neurodevelopment.

Notably, very few studies have examined the association between maternal childhood adversity and infant neurodevelopment as a function of early parenting behaviors. Such studies might elucidate that early parenting behaviors are a key point of intervention for

breaking the cycle of adversity that is especially maintained in lower SES and minority populations. Black Americans, for example, experience twice the rate of poverty of White Americans [8], and results from studies using the Centers for Disease Control and Prevention's ACEs module indicate that Black Americans are also disproportionately exposed to ACEs when compared to their White counterparts [24]. Although social scientists have dedicated many years to unfolding the short- and long-term consequences of early life adversity, most of the research in this area has relied on cross-sectional studies and retrospective accounts. It is therefore crucial that the influence of ACEs on parenting and infant neurodevelopment is examined using prospective research designs in samples that may be at increased risk. The present study attempts to fill this gap in the literature.

This pilot study aimed to explore the effects of maternal ACEs on infant neurodevelopment. It was hypothesized that maternal experiences of childhood abuse and neglect would predict lower scores on measures of infant neurodevelopment at three months of age. Secondly, this study aimed to examine whether positive parenting behaviors would mitigate the effect of maternal childhood adversity on infant neurodevelopment. It was therefore hypothesized that the association between maternal ACEs and infant neurodevelopment would be weaker in cases where mothers displayed more positive parenting behaviors.

OUR STUDY

Study participants were African American mother-infant dyads (N=59) currently enrolled in a larger, ongoing study focusing on infant development. All participants were originally recruited during pregnancy from hospitals in a large metropolitan city in the southeastern United States. Inclusion criteria for the pregnancy study were: 1) African American race (as determined via self-report); 2) Maternal age of 18-40 years; 3) No chronic medical conditions; 4) Singleton pregnancy; and 5) Fluency in written and spoken English. During their participation in the pregnancy study, mothers were asked if they would be willing to be contacted for future studies. Women were then recruited for the infant study if their infants were born without congenital disorders. Informed consent was obtained from the women prior to participation in the infant study using procedures approved by Emory University's Institutional Review Board. Participants were included in the current study if mothers reported on their history of childhood adversities and mothers and infants completed the postnatal follow-up study visit when the infant was 3-months-of-age.

Data for the present study were collected at two study time points: during pregnancy (T1) and when offspring were 3-months-of-age (T2). Ongoing follow-up visits occurred at 6-months (T3), 12-months (T4) and 18-months (T5) of age, but these time points were not included in the present study due to insufficient sample size to date. Maternal demographics (i.e., age and socioeconomic status) and history of adversity were collected at T1 via questionnaires and medical chart record abstraction. At T2, mothers and infants completed videotaped observation tasks and infants were administered an assessment of mental development status. Study visits were conducted by trained Master's level research assistants either at participants' homes or during a visit to the laboratory at Emory University.

Sociodemographic Factors and Statistical Controls

Information about mothers' age in years and socioeconomic status were collected at T1 and examined as potential control variables. Socio-economic status was operationalized as the mother's federal poverty level and highest level of education.

Maternal Childhood Adversity

Maternal adversity was assessed at T1 using the Childhood Trauma Questionnaire (CTQ) [25], which asks about experiences of abuse and neglect during childhood and adolescence and has been shown to yield reliable and valid retrospective assessments [26]. Responses were collected on a 5-point Likert scale, with response options ranging from Never True [1] to Very Often True [5]. A visual inspection of the CTQ score histogram suggested scores were non-normally distributed. Therefore, dichotomous indicator variables were derived to denote maternal history of physical abuse, sexual abuse, and neglect, where 0 = Never and 1 = Some Exposure.

Early Parenting Behaviors

Parenting behaviors were assessed using five-minute free-play situation videos for mother-infant dyads obtained at T2. An adapted version of the Three-Bag Assessment [27] was used to code each interaction task video for maternal sensitivity and positive regard. Maternal sensitivity refers to the mother's capacity to recognize the child's emotional state and respond with comfort, consistency, and warmth, and positive regard refers to behaviors such as having a warm tone or smiling [28]. Each parenting behavior variable (i.e., maternal positive regard and sensitivity) was coded on a scale ranging from 1 to 4 points, where 1 represents no evidence of the particular variable, and 4 represents the highest relative demonstration of that variable. A single positive parenting summary score was computed by combining the two positively-valenced domains and could range from 1-8, where higher scores indicated more positive parenting behaviors.

All coders underwent an initial coding training sequence to achieve independent levels of greater than or equal to 80% reliability for previously determined "gold standards" of each coded variable. Coders included trained graduate and undergraduate students who were blind to levels of maternal distress and infant mental development. A trained graduate student supervised ongoing reliability of 20% of the coded videos, maintaining greater than or equal to 70% reliability for each coded variable across interaction tasks, and holding weekly coding meetings, as needed. Intraclass correlations of inter-rater reliability on all coded variables ranged from 0.81 to 0.94.

Infant Neurodevelopment

Infant neurodevelopment was assessed at T2 using the Bayley Scales of Infant and Toddler Development, Third Edition (Bayley-III) cognitive and motor subscales [29]. The Bayley-III was designed to evaluate developmental functioning through a series of standardized items. After each assessment, raw scores for each subtest were calculated by the test administrator and double-scored by two trained undergraduate research assistants. Raw scores were then converted to standardized scores to determine each baby's cognitive and motor skills composite scores, which were used in current study analyses. The cognitive composite score reflects the infant's ability to think, react, and learn about the world around him or her. The motor skills composite score combines gross motor and fine motor skills, which gauge how well the infant can manipulate objects with his or her hands and examines static positioning, movement of limbs, and balance. The Bayley-III Scales have been well validated and are a reliable indicator of infant mental status [30].

Data Analyses

Descriptive analyses were performed to assess sample characteristics. Data were examined for multicollinearity and normality using univariate procedures, and bivariate analyses were conducted to identify statistical controls. To assess study aims and hypotheses, a series of multiple linear regression analyses were performed using maternal childhood adversity and parenting variables as predictors of infant neurodevelopmental outcomes at T2 (i.e., cognitive composite score and motor skills composite score, respectively). To test moderation hypotheses, interaction terms were computed by centering each independent variable of interest and obtaining the product (i.e., maternal physical abuse $\times$ positive parenting, maternal sexual abuse $\times$ positive parenting, and maternal neglect $\times$ positive parenting, respectively). Multiple linear regression analyses were then conducted in SPSS [31] to assess whether maternal childhood adversity interacted with parenting behaviors to predict infant neurodevelopmental outcomes at T2. Estimates were considered statistically significant at $p < 0.05$.

FINDINGS

The average age of mothers in this sample ($N=59$) was 25.34 ($SD = 5.40$). The majority of the sample had a high school diploma or GED ($n = 28$; 47.5%) and were at less than 100% of the federal poverty line ($n=23$; 39%). Approximately one third of mothers reported experiencing physical abuse ($n=20$), sexual abuse ($n = 20$), and/or physical neglect ($n=22$), and the average positive parenting score was 6.78 ($SD = 1.34$). Additional sample characteristics are reported in Table 1.

Preliminary analyses examining maternal age, education, and income as covariates were conducted using Pearson correlations and independent samples t-tests. Results indicated a significant correlation between maternal age and infant motor skills composite scores at 3-months ($r = -0.24$, $p = 0.048$), with older mothers' infants having lower scores. Maternal age

was not significantly associated with infant cognitive scores ($p = 0.59$). Additionally, there were no significant differences in either motor or cognitive scores by maternal education or income level ($ps > 0.05$).

Table 1. Sample characteristics (N=59)

Variable	n	%	Mean (SD)	Range (Min-Max)
Education				
Some High School or Less	6	10.2		
High School Diploma/GED	28	47.5		
Some College/Technical School	14	23.7

¹ All interaction effects models run separately. Models using motor composite scores as the primary outcome control for maternal age.

To examine study aims and hypotheses, a series of multiple linear regression analyses were performed. Results indicated that there were no significant main effects of maternal childhood physical abuse, sexual abuse, or neglect on infant cognitive or motor skills development at 3-month follow-up ($p > 0.05$; see Table 2). There was also no significant main effect of positive parenting on infant cognitive or motor skills at 3-months-of-age. Finally, results indicated that there were no significant interaction effects between maternal childhood adversity and parenting ($p > 0.05$; see Table 2).

DISCUSSION

ACEs have been cited as significant environmental risk factors for a host of negative outcomes. Minority populations and those who reside in socio-economically depressed areas are disproportionately exposed to ACEs [8, 24], and studies have provided evidence that ACEs may have intergenerational effects on offspring development [13, 14]. There is evidence that maternal ACEs decrease maternal responsiveness, sensitivity, and positive affect, which in turn, impede infant neurodevelopment [17]. Recently, associations between maternal ACEs and child brain anatomy have been observed [32]; but the majority of research in this area has relied on cross-sectional studies and retrospective accounts. This study aimed to examine associations between maternal childhood abuse and maltreatment and infant neurodevelopment and assess whether early parenting behaviors moderated these associations. Preliminary findings from this pilot study, however, suggest no main effects of maternal adversity on infant neurodevelopment at 3-months and indicated no significant interaction effects between maternal adversity and early parenting behaviors.

It is important to acknowledge several possible methodological limitations in the current study. First, this pilot study was limited in its ability to detect significant effects due to a small sample size, which was supported by post hoc power analyses ($1 - \beta = 0.31$). Secondly, it is possible that infant neurodevelopment scores at 3-months of age are less reliable and stable than later time points. The Bayley manual provides test-retest reliability values that range from .67 to .80 for infants aged 2 to 4 months; but these indices were calculated using very short retest intervals (approximately 6 days). There will likely be significant developmental changes as time progresses since milestones are achieved more rapidly in the early stages of life [33], and scores are expected to stabilize. Thus, by 6- and 12-month follow-up, Bayley scores may be more reliable and valid.

It is also possible that there are nonlinear associations between maternal childhood abuse and neglect, where effects at the tail ends of the distribution have the greatest effects on infant neurodevelopmental outcomes. The present study assessed maternal history of adversity using the CTQ but derived dichotomous indicators of abuse and neglect, because of the non-normal distribution of scores. Dichotomous variables inherently have no range and less variability, which may deflate the significance of effects. Mothers with severe levels of exposure to abuse and neglect, however, may be at greatest risk, as previous researchers have noted worse outcomes among individuals with severe exposure to adversity [3, 34]. Future studies should therefore consider the severity of experiences to identify potential risk thresholds for negative outcomes.

Finally, parenting measures, while objective, were conducted in participants' homes under video-taped conditions. The literal act of video-taping the mother-child interaction subsequently necessitates that mothers are highly aware of their behaviors, words, and emotions, particularly those that are directed towards their 3-month old infant. While this paradigm allows for researcher standardization (across all observed videotaped home-visits of participants) it also leaves room for artificially positively-valenced observations. This artificial increase may have contributed to mothers' high scores on sensitivity and positive regard, the two variables that were captured within our positive parenting variable. Mothers' positive parenting ranged from 1 to 8, but on average, fell at 6.78 (1.34). Mothers may have been more likely to behave positively towards and around their children, due to 1) the presence of the study researchers, 2) the presence of video cameras, and 3) the knowledge that their behaviors were being captured for purposes of scientific study. As such, it is possible that we could not adequately capture a full range of parenting behaviors. This phenomenon can be likened to the Hawthorne Effect, or the concept that research study participants often change their behavior simply as a function of the fact that they are observable participants [35]. This phenomenon has been reported in parenting intervention programs [36], and previous studies have hinted at a need to control for the emergence of the Hawthorne Effect, particularly when studying young children [37]. To address this issue, future studies could incorporate self-report measures of parenting for purposes of reliability and comparison. Although parents are often unreliable raters of their own behaviors and often rate themselves more positively than other reporters [38], the combination of observer ratings and self-report may be preferable to including only one of these methods on their own. Lastly, it is possible that 3-months of age is too young to elicit a varied range of behaviors from mothers. We would expect more variability in infant temperament and maternal parenting as the infants age [39].

Despite the above stated limitations, this study has notable strengths. First, the usage of a prospective longitudinal design is quite promising and will provide the ability to examine rates of infant neurodevelopment using growth curve analyses in the future. Data collection on our postnatal cohort will continue at 6, 12, and 18 months, with a goal to eventually enroll study participants in a second longitudinal study with time points at 2, 3, 4, 5, and 6 years. We are also utilizing a well-validated, reliable tool for the assessment of infants' neurodevelopment. Infant mental assessments are notoriously challenging, but the Bayley-III is widely used and is frequently cited as a reliable and valid measure for this early infancy age group [30].

Strengths and limitations considered, one possible interpretation of these preliminary findings is that despite having experienced adversity, most mothers are actually engaging in positive parenting strategies. At least one-third of study participants experienced some form of abuse or neglect, yet positive parenting scores were elevated (see Table 1). It is therefore possible that these mothers have already taken the steps necessary to disrupt the cycle of adversity via their interactions with their child. As such, parenting behaviors may still be viewed as a key point of intervention in breaking the potential intergenerational effects of ACEs among at-risk populations who are disadvantaged and disproportionately experience early life stress. Future studies will explore child neurodevelopment and parenting behaviors at later time points in hopes of elucidating a clearer relationship, as children's neurodevelopmental patterns become more reliable and valid, and parenting behaviors become more variable (in response to children who are more mobile and verbal).

Furthermore, maternal childhood adversity and parenting behaviors may predict the rate of neurodevelopment over the first year of life, rather than mean levels of cognitive and motor skills scores at 3-months of age, as reflected by composite scores. Expansion of our pilot study to a larger body of work is promising both analytically and clinically, and ongoing work on this pilot study will delve further into breaking this cycle of risk.

ABSTRACT

Adolescent mothers are at risk of developing mental health issues, living in poverty, dropping out of high school, and becoming unemployed, which may lead to compromised parenting skills. Adolescent mothers have the potential to use effective practices, such as dialogic reading (DR), when given the appropriate levels of support and education to facilitate their children's language and literacy development. The purpose of this chapter was to evaluate the feasibility of teaching DR strategies to adolescent mothers as measured by DR strategy use during shared book reading with their children. The secondary purpose was to determine the impact of adolescent mothers' implementation of DR strategies on their preschool children's single word vocabulary. A single subject multiple baseline across behaviors research design was implemented with one adolescent mother and her twin boys. Based on visual analysis of graphical representation of the data, it was determined there was a functional relation between educating an adolescent mother on DR and her implementation of DR strategies during shared book reading with her children, depending on the DR strategy. However, children's receptive and expressive scores on the individual book assessments decreased from baseline to intervention. These results provide preliminary evidence that adolescent mothers have the potential to implement new strategies during shared book reading when provided with direct support. Future research should focus on developing an intervention for adolescent mothers and their children that enhances children's language and literacy development.

INTRODUCTION

In 2014, nearly 250,000 infants were born to teenage mothers aged 15-19 years in the United States [1]. Birth rates were highest for Hispanic adolescents ages 15 to 19 years, followed by black adolescents, and then white adolescents [1]. Young women characterized by risk factors across several developmental domains have been found to be at an increased risk for teenage pregnancy [2]. These factors include being reared by a teenage mother, being born into a single parent family, a high rate of exposure to parental change, educational underachievement, conduct issues, early onset of menarche, engaging in high rates of sexual activity, and involvement with deviant peers [2]. While rates of teenage births have steadily declined from 52% in 1991 to 9% in 2013 [1], teenage pregnancy remains a serious issue requiring attention within a life course developmental model due to the risk factors associated with childhood and adolescence and the negative and lasting effects it has on teenage mothers and their children (figure 1 depicts the cycle of teenage pregnancy).

Figure 1. Cycle of adolescent pregnancy.

Teenagers who become parents during their adolescent years are subject to multiple risk factors. In fact, the leading cause of school dropout among adolescent girls is pregnancy or parenthood, with only 40% of teenage mothers finishing high school, and less than 2% of teenage mothers finishing college by age 30 years [3]. Low achievement in education may leave adolescent mothers at a disadvantage in the job market, therefore leading to financial hardships [4]. Eighty-three percent of parenting adolescents come from poor or low-income families and more children born to adolescent mothers live in poverty than children born into

traditional families [4]. Mothers living in poverty and with little education are less likely to provide the necessary resources, support, and care to their children [5].

Mental health concerns are prevalent among the adolescent parent population. It has been widely documented that depression rates in young mothers are much higher compared to rates in adult mothers and typical adolescents [5]. Stressors connected to depression among teenage mothers are described as high levels of parenting stress, little to no social support, and weight concerns [4, 6]. As depression rates increase, adolescent mothers display less positive parenting practices, such as maternal warmth and sensitivity, contingent responsiveness, and general talkativeness [5].

The lack of educational achievement, persistence of financial difficulties, and high rates of depression reported by adolescent mothers have an impact on parenting behaviors and ultimately child development [7]. Many factors such as high depression rates, low socioeconomic status (SES), low levels of resources, and higher rates of health complications (e.g., low birth weight) affect children's cognitive, language, and temperament development [7-10]. Children of teenage mothers are at-risk for developing disorganized attachment patterns with their mothers as infants [9], perform less well on emerging literacy and math measures as two-year-olds compared to those born to adult parents [8], and score lower on language performance measures as toddlers [11]. Furthermore, children of teenage mothers are at risk for language delays as toddlers when compared to children born to adult mothers [11] and of being retained a grade in elementary school [10].

Keown and colleagues [11] reported increased maternal intrusiveness (i.e., ill timed, restrictive, and directive maternal behavior) and lack of verbal stimulation and involvement accounted for the difference in early expressive and receptive language competence between children born to adolescents and children born to adult mothers. Expressive and receptive language delays in children of teenage mothers are also linked to low maternal ability and a poor quality linguistic home environment [10].

Therefore, interventions focused on the literacy practices and reading behaviors of teenage mothers when interacting with their children must be developed [12]. There are several studies that attempt to understand and facilitate interactions between teenage parents and their children. For example, Neuman and Gallagher [13] coached teenage mothers on behaviors and strategies during literacy-related play activities. They reported an increase in the labeling, scaffolding, and contingent responsivity used by teenage mothers, as well as a statistically significant increase in vocabulary measures in the children [13].

In a study conducted by Scott and colleagues [12], teenage mothers were coached on emergent literacy skills to be used when reading to their children, including teaching vocabulary, phonemic awareness, and print concepts. Participants demonstrated a statistically significant improvement before and after the intervention in the use of questioning, vocabulary, and book and print features. This study, along with Neuman and Gallagher's [13] study, suggests a change in parent reading strategies is possible when taught by a clinician. However, the effect of these skills on the teenage mothers and their children have not been specifically explored.

Dialogic reading (DR) is a specific type of shared interactive reading intervention reported to enhance preschool children's oral language [14, 15]. DR is designed to reduce adults' straight reading from the book and encourage children to become more participatory during the reading experience [14]. During DR, adults use a series of prompts (completion, recall, open-ended, wh-questions, and distancing; i.e., CROWD) and a prompting hierarchy

(prompt, evaluate, expand, repeat; i.e., PEER) to facilitate children's storytelling during the shared reading experience. First, the adult prompts the child using one of the CROWD prompt types centered around a specific word, illustration, or word in the book. Then, the adult evaluates the child's response, providing positive feedback for a correct response, and corrective feedback for an incorrect response. Next, the adult expands the child's response by adding some linguistic element, an adjective or phrase, to enhance the child's response. Finally, the adult repeats the original prompt so that the child may repeat the expanded response. During the first step (i.e., prompt), a variety of prompts may be used (CROWD): completion prompts encourage children to complete an utterance the adult begins, often using a repeated text element from the book; recall prompts are used to ask children about events that occurred previously in the story; open-ended prompts are used to ask children what is happening in a picture, encouraging children to respond more than yes/no; wh-questions highlight specific vocabulary or language features utilizing what, where, when, why, and who questions related to the story's illustrations; and distancing prompts are utilized to connect the book's events to children's real life experiences [14]. These behaviors are adopted to enhance the sophistication of a child's descriptions of a story's characters, objects, and plot.

The effectiveness of this intervention has been evaluated across populations and contexts. Whitehurst and colleagues [15] first reported an effect on expressive language ability with middle to upper-SES participants. These effects were later seen with children from low-income families [14]. Children exposed to this intervention were also found to be more likely to exhibit a higher mean length of utterance, higher frequency of phrases, and a lower frequency of single words [15].

While researchers have reported an increase of DR strategies present in shared book reading by adults when trained to use the strategies, it is the level of implementation of DR that has been found to positively influence children's oral language [14]. Yet, there is limited report of low-income parents' responses to a DR training. Furthermore, researchers who have included low-income families in their studies have neglected to track the fidelity of the use of DR strategies when parents are trained to use them [16]. Compliance to the intervention has been reportedly tracked through parent interviews after intervention, reading logs filled out by parents during the intervention, and parent surveys but not by tracking of implementation fidelity by researchers [16].

Breaking the Cycle

Because adolescent pregnancy and parenting is such a complex and involved issue, limited investigation has been done to understand what interventions can disrupt this cycle. To break the cycle of economic, educational, and developmental delays, it is essential to understand what specific interventions and support are most beneficial for adolescent mothers and their children - it may be that the use of a literacy program is advantageous, providing multiple opportunities for communication between mother and child [12]. In a study conducted to investigate the factors that lead to an achievement gap among children born to adolescent mothers, Luster and colleagues [10] found the most successful children were those that experienced more supportive care and higher levels of parenting, were read to frequently, and had mothers who progressed further in their schooling. While young mothers are heavily

impacted by early onset pregnancy, the majority of adolescents feel a sense of maternal responsibility towards their baby, indicating they are not receiving the support and education necessary to offset the many effects their children are reportedly experiencing [2, 10].

Immediate concern needs to be focused on literacy and language development of adolescent mothers' children because of the documented negative impacts that early onset parenting has on children's language and literacy skills [7, 9, 10]. Therefore, interventions should focus on training teenage parents on how to expose their children to literacy and its importance [6]. Research has repeatedly shown that professionals and caregivers are able to learn the DR protocol, which can positively influence oral language and literacy development in preschool-aged children [14, 16]. However, there is a lack of information on adolescent parents' ability to learn and implement the DR strategies with fidelity.

The primary purpose of this study was to evaluate the feasibility of teaching DR strategies to adolescent mothers as measured by DR strategy use during shared book reading with their child. The secondary purpose was to determine the impact of adolescent mothers' implementation of DR strategies on their preschool children. The research questions are: 1) To what extent does a DR intervention taught to adolescent mothers in a one-on-one setting affect their shared reading behaviors as measured by their use of the DR strategies as measured by a fidelity checklist? 2) What is the impact of an adolescent mother's fidelity of implementation of DR strategies during a shared book reading and her child's single word expressive vocabulary? 3) What is the impact of an adolescent mother's fidelity of implementation of DR strategies during a shared book reading and her child's single word receptive vocabulary? 4) What are the perceptions of the teenage mothers regarding the goals, procedures, and outcomes of the DR intervention as measured by a survey?

OUR STUDY

A single subject multiple baseline across behaviors a priori research design was utilized to measure the impact of a DR intervention on the use of the CROWD and PEER strategies implemented by adolescent mothers during shared book reading. Phase changes were based on predetermined time points, instead of based on criterion. Each reading session was recorded to determine inter-observer agreement and training fidelity. Reading behaviors were coded live during each session or from the video as necessary to track frequency or percentage of use.

Recruitment Procedures

After IRB approval, three adult participants and their children were recruited from a charter school in the southeastern United States. The researcher visited the regularly scheduled playgroup with a staff member to explain the study, potential benefits and risks, inclusion criteria, and compensation to potential participants. Inclusionary criteria for mothers were as follows: 1) 15 to 19 years old, 2) have a child 2 to 5 years old, and 3) be enrolled in the teen parent program at the charter school. All eligible participants were 18 years or older, so they signed consent immediately. While three participants signed consent, one participant

withdrew from school and another did not meet the 50% attendance criteria during the baseline phase, so they were excluded from the data analysis. Only one adolescent mother, Isabel (all names included in this paper are pseudonyms), participated in the entire study.

Participants

Isabel was an 18-year-old African American mother of twin boys, Jack and John. Isabel was matriculated in 11th grade and self-reported a grade point average (GPA) of 2.8 at the beginning of the study. She was fifteen when she had her twin boys. Isabel lived at home with her parents and spoke English only. She reported an annual household income of less than \$24,999, which indicates that she was from a low SES household. When asked about her home literacy practices, Isabel reported she read to her children daily, taught her children new words “all the time” (quoted from Isabel), owned four picture books for her children at home, and never took her children to the library. Isabel scored a total of 54 out of a possible score of 94 on the researcher developed Perceptions of Reading Abilities. Her responses ranged from 1 (never) to 5 (always) on the individual components of the survey. This result indicated that Isabel had a moderate perception of her capabilities in reading abilities, such as sounding out words, answering questions based on a passage, and reading fluently. Isabel's Total Reading standard score was 73 on the Woodcock Reading Mastery Test (WRMT-R/NU; 17), almost two standard deviations from the mean, which indicated a moderate to significantly below average score.

Jack and John were twin brothers who were 33 months at the start of the study. They were both African American, spoke English at home, and had a medical diagnosis of asthma. Jack had a total language score of 95 on the Peabody Language Scale 5th Edition, with a 93 on the auditory comprehension subtest and a 97 on the expressive communication subtest. He had a standard score of 106 on the PPVT-4 and a standard score of 100 on the EOWPVT-4. John received a total language score of 96, with a 98 on the auditory comprehension subtest and a 95 on the expressive communication subtest. He earned a standard score of 92 on the PPVT-4 and a 92 on the EOWPVT-4. All language scores for both children were in the average range. During the pretesting period, it was observed that both children were easily distracted and had difficulty attending to one task for a long period of time.

Setting

This study was conducted at a charter school in the southeastern United States during regularly scheduled weekly playgroups for adolescent mothers and their children to provide an opportunity to interact during the school day and during group therapy for adolescent mothers. For this study, arrangements were made prior to the start of the intervention that the participants could attend an intervention session during their group therapy period so there would be two intervention sessions per week. Participants also attended a newly created group specific to the study during the intervention program, instead of their regular weekly playgroup.

Independent Variable

Isabel was educated on each reading strategy by the researcher. The training consisted of: 1) naming the strategy, 2) defining the strategy, 3) providing examples, and 4) answering questions. Isabel received a handout which summarized the reading strategy during the first session of each strategy. Books were provided and scripted with 12 CROWD prompts each. Isabel was asked to read the entire book and include the scripted prompts. During the sessions following the introduction of a new DR strategy, the researcher reviewed the DR strategy prior to the book reading using the same components of the training (i.e., naming the strategy, defining the strategy, providing examples, and answering questions). Isabel was reminded and encouraged to continue use of the previously learned reading strategies, as the DR steps are cumulative.

The adherence to the DR intervention was assessed by a trained research assistant (RA B) according to the following elements: 1) session started with a hello song, 2) children were invited to play, 3) during training or review, the strategy was named, 4) during training or review, the strategy was defined, 5) during training or review, examples were provided 6) during training or review, any questions were answered, 7) children were invited to read a book, 8) the parent read a book to children together, 9) children were invited to play, 10) feedback was provided, 11) new questions were answered and 12) session ended with a goodbye song. Twenty-five percent of videotaped sessions were observed and scored. The sessions were randomly selected prior to the start of the study. Fidelity was measured by the number of behaviors observed divided by the total number of behaviors that should have been observed and multiplied by 100. Fidelity was 91.7%.

Materials

Seven books were randomly selected from the “Read together, talk together” kit as done in past studies. (RTTT; 17). The books used included “A summery saturday morning” (1998), “Pigs aplenty, pigs galore!” (2008), “The wolf’s chicken stew” (1996), “I took my frog to the library” (1992), “The dinosaur who lived in my Backyard” (1990), “Spike in the city” (2000) and “Oonga Boonga” (1990). One book was provided for baseline without any alterations. Five intervention books were used during the intervention phase. Each intervention book was prepared with twelve scripted questions based on CROWD prompts taped into the book following the written text. There were at least two scripts of each CROWD prompt type. Five vocabulary words were targeted through these scripts. The researcher consulted the RTTT teacher notes to choose the book specific vocabulary. Vocabulary words had to be mentioned in the text, as well as depicted in the illustrations. One book (book 7) was provided for generalization without any alterations on the last intervention session.

Procedures

After IRB approval and consent to participate, Isabel was individually tested on the Reading Comprehension Cluster of the Woodcock Reading Master Test Revised-Normative

Update (WRMT-R/NU) during her group therapy sessions. She also completed the self-efficacy questionnaire on her reading abilities and a demographic survey. Each child was assessed using the PLS-5, EOWPVT-4, PPVT-4, and near-transfer receptive and expressive vocabulary tests.

After testing was complete, Isabel entered the baseline phase for five sessions for the first behavior (i.e., prompt), eight for the second behavior (i.e., evaluate), eleven for the third behavior (i.e., expand), and fourteen for the fourth behavior (i.e., repeat). After baseline, Isabel entered the intervention phase which included DR training and using pre-scripted books. After the intervention, Isabel entered the generalization phase (see Table 1).

Table 1. Dialogic reading intervention overview

Session	Focus	Book
Baseline sessions 1-5	Read as you normally would	1
Intervention sessions 1-3	Prompt your child (i.e., CROWD prompts)	2 & 3
Intervention sessions 4-6	Evaluate what your child says	2 & 4
Intervention sessions 7-9	Expand what your child says	2 & 5
Intervention sessions 10-12	Repeat the prompt	2 & 6
Generalization sessions 1-2	Read without intervention supports	7

Baseline. Baseline data were taken for five sessions during the biweekly playgroups. Isabel was instructed to read to her children as she normally would with no intervention present. One book was used only for baseline. After five predetermined baseline sessions, the DR intervention for the first behavior began.

Intervention. The intervention was an eight-week program completed during the biweekly playgroup sessions. Each session lasted 30 minutes and was led by the researcher. Three sessions were dedicated to each strategy (i.e., prompt, evaluate, expand, repeat). During the first of these three sessions, the researcher educated Isabel on the strategy (see Independent Variable) and Isabel practiced the strategy through the reading of one book (i.e., *Pigs Aplenty*, *Pigs Galore!*) to her children. During the next two sessions, the strategy was reviewed and Isabel read a new book to her children to practice the strategy. A new book was introduced for each new reading strategy (i.e., four new books). Each session was structured consistently, but the focus of the session differed every three sessions (see Table 1 for an overview of the intervention). The following schedule was followed every session: 1) hello song, 2) training/review of reading strategy, 3) book reading, 4) discussion and feedback for the mother during playtime and 5) goodbye song.

Generalization. Isabel was provided a new book on the last intervention session and was asked to prepare to read to her children using the DR reading strategies. Isabel was videotaped while reading to her children without the support that was present in the intervention (i.e., unscripted books, no feedback from the researcher, and no review of dialogic reading strategies). This occurred during playgroup, just as baseline did, for two sessions.

Data Analysis

Isabel's use of the DR strategies was coded by the first author to track implementation fidelity of the CROWD and PEER strategies. One undergraduate research assistant was trained to code prior to the start of the study by observing and coding sample videos with direct instruction from the first author to criterion. The research assistant had to reach 80% agreement with the first author before she could begin coding [19].

During baseline and generalization, questions posed by Isabel were coded as any of the CROWD prompts or as "other" questions (e.g., yes or no questions, questions eliciting pointing) based on Isabel's intentions. During intervention, however, the books were scripted with CROWD prompts. Isabel's reading behaviors were coded based on whether she asked the scripted questions. Any questions outside of the twelve scripted prompts were coded as any of the CROWD prompts and "other" questions as determined by the coder. CROWD prompts were measured as an average frequency per phase.

The presence of the PEER hierarchy was coded as to whether Isabel used each strategy for all phases. Evaluate, expand, and repeat strategies were measured as average percentages per phase (number of times the strategy was used divided by number of opportunities for the strategy to be used multiplied by 100). The number of opportunities was equal to the number of questions Isabel asked during the book reading, because she had the opportunity to use the strategies anytime she asked a question.

Inter-observer agreement (IOA) was established through the coding of 25% randomly selected videotaped sessions by a trained research assistant which was compared with the original coding sheets. A minimum of 80% agreement was required for IOA. Inter-observer agreement was calculated by dividing the amount of agreements by the total sum of disagreements and agreements between the raters and multiplying by 100. Reliability was 85% between the first author and the research assistant. Disagreements in the coding were resolved by the first author and the research assistant.

Effects of the DR intervention on the reading behaviors of an adolescent mother were examined through visual analysis [19]. Line graphs were constructed to display the data for each behavior. The four steps for conducting visual analysis were as follows: 1) "document a predictable baseline pattern of data", 2) "examine the data within each phase of the study to assess the within-phase patterns," 3) "compare the data from each phase with the data in the adjacent phase to assess whether manipulation of the independent variable was associated with an effect," 4) "integrate all the information from all phases... to determine whether there are at least three demonstrations of an effect at different points in time" (which in the present study were baseline, intervention, and generalization) [19]. The features examined to assess the effect of an intervention were: 1) level, 2) trend, 3) variability, 4) immediacy of the effect, 5) overlap and 6) consistency of data patterns across phases [19]. Changes in level (the average of the data in a phase), trend (the slope of the line of best fit within a phase), and variability (the range of data surrounding the best-fitting straight line) were displayed on each graph and examined. Data patterns across phases (immediacy of effect, overlap, and consistency of data in similar phases) were examined to further determine the effect size of the intervention. Immediacy of effect is measured by the change in level in the last three data points and first three data points in adjacent phases; a more rapid effect signifies a stronger relationship between the intervention and effect. Overlap refers to the amount of data that

converges in between phases; the larger the separation between data of two neighboring phases, the more convincing it is that there has been an effect [19]. Consistency of data in similar phases will not be considered in the present study because each phase of this study is unique. The steps outlined above were followed using the assessment features to determine what effect the DR intervention had on adolescent mothers’ reading behaviors.

Figure 2. Isabel’s use of DR strategies.

Isabel was asked to complete a social validity survey [20] at the end of the intervention. The survey measured Isabel's views of the goals, procedures, and outcomes of the study through seven items on a seven point Likert scale and four open ended questions. The survey included seven questions to be answered on a seven point Likert scale. Scores were totaled and an average score was calculated.

During the last intervention session of each book, the children were assessed on the five book-specific vocabulary terms targeted in the books that were read through an expressive and receptive task. For the expressive test, the children were shown a scanned illustration from the book depicting each vocabulary word and were asked "What is this?" The administrator waited five seconds for a response before recording a non-response. Each verbal response was recorded and the total number of correct responses was scored. For the receptive test, children were shown four scanned pictures- one of them was the targeted vocabulary word, and three were foils. The administrator said, "Point to the ____." and again waited five seconds before recording a non-response. Each response and the total number of correct responses were recorded. Prior to the start of the study and after the intervention was complete, the children were assessed on all twenty vocabulary words targeted in the four intervention books. The same procedures were used as in the individual book vocabulary tests.

FINDINGS

Research question 1 (see figure 2). During the baseline, there was a low degree of variability, with a mean of 0.8 (range 0 to 4), and a moderate downward trend on the issue of prompt. Isabel was then trained to use the different types of prompts as established by the DR protocol (i.e., CROWD). Following intervention, there was an immediate increase in the level of the variable ($M = 11.58$), little variability, and no overlap with the baseline. The level decreased ($M = 5$) from intervention to generalization.

Evaluate. During the baseline, there was a high degree of variability with a mean of 21% (range 0% to 72%) and a moderate negative trend. Immediately following intervention, there was a rapid increase in the level of the dependent variable ($M = 74\%$) with moderate variability, and 44% overlap with the baseline. The level slightly decreased ($M = 71.25\%$) from intervention to generalization.

Expand. During the baseline, there was minimal variability with a mean of 3% (range 0% to 9.10%) and a moderate negative trend. Immediately following intervention, there was a slow increase in the level of the dependent variable ($M = 13\%$) with little variability, and 17% overlap with the baseline. The level from intervention to generalization slightly decreased ($M = 10\%$).

Repeat. During the baseline, there was minimal variability with a mean of 0.65% (range 0% to 9.10%) and a low negative trend. Immediately following intervention, there was a rapid increase in the level of the dependent variable ($M = 49\%$) with little variability and no overlap with the baseline. The level decreased ($M = 32.5\%$) from intervention to generalization.

Research questions 2 and 3. To determine if there was an effect of the adolescent mother's training on DR behaviors and her sons' receptive and expressive vocabulary, the mean scores on the near-transfer assessments for the baseline and intervention phases per

child were calculated. Children’s vocabulary scores were reported per child. Table 2 demonstrates the book-specific vocabulary per phase and per book. Both John and Jack’s expressive scores were 3 (out of 5) for baseline and 2.25 (out of 5) for intervention. Their receptive scores were 5 (out of 5) for baseline and 3.25 (out of 5) for intervention. The expressive and receptive near-transfer vocabulary decreased from baseline to intervention in both children.

Table 2. Book-specific vocabulary per phase

Book		Vocabulary targeted			
Baseline					
Book 1	Cat	Dog	Bike	Goose	Sandals
Intervention					
Book 2	Oatmeal	Plane	Pizza	Broom	Bed
Book 3	Wolf	Chicken	Pancakes	Doughnuts	Cake
Book 4	Librarian	Card catalog	Skin	Pelican	Hyena
Book 5	Dinosaur	Basketball	School bus	Tent	Kite
Book 6	Leash	Parking meter	City	Frisbee	Skateboard

Research question 4. The adolescent mother’s experience related to the DR intervention was evaluated through a 7-item social validity questionnaire. Samples of Isabel’s answers to the open-ended questions of the survey were included to address the aspects of the intervention that were most and least enjoyable. Isabel responded with an average of 6.42 (range 6 to 7) on the seven items, indicating a high level of acceptance of the DR intervention. Responses to open-ended questions also indicated positive reactions to the experience. Isabel reported that she enjoyed the intervention because “[her] boys are learning more vocabulary” and that she “learned new ways to read to [her] boys.”

DISCUSSION

Adolescent mothers have the potential to use effective practices when given the appropriate levels of support and education to facilitate their children’s language and literacy development [3, 21]. Dialogic reading has been shown to be effective in developing children’s expressive and receptive language skills when implemented by a variety of adults, including parents [14-16]. However, there are limited reports related to implementation of DR strategies and the degree of fidelity when implemented with low SES adolescent parents.

We examined the feasibility of teaching DR strategies to an adolescent mother from a low SES home by measuring her use of DR strategies (i.e., CROWD and PEER) during shared book reading with her children. The data indicated that when trained on the four DR strategies separately and provided with consistent feedback and in-book scripts, the adolescent mother was able to learn and implement the DR strategies more frequently than in baseline. The data suggested a highly effective intervention on the prompt and repeat DR strategies for Isabel, and a moderately effective intervention on the evaluate and expand DR strategies. These results are consistent with previous studies in which adults have been trained, specifically parents, to implement DR strategies during shared book reading [16]. Given that adolescent mothers have responded well to other direct supportive services, such

as prenatal fitness, stress management classes, and maternal nutrition classes, when employed in their school curriculum [21], they demonstrate potential to learn and implement new strategies. This potential coupled with adolescent mothers' instinctive maternal care and sense of responsibility for their children [22] may begin to explain Isabel's success in implementing the DR strategies. It may be important to note that the "expand" strategy had the least immediate increase out of the other DR strategies, which is consistent with past studies [16]. This may indicate that this strategy is the most difficult to implement because it requires the adult to have knowledge on what components can be provided in an expansion, a skill typical parents, especially young mothers, may not obtain. In future studies, this strategy may require additional training or support to be implemented accurately.

During generalization, there was a decline for all behaviors. The consistency in Isabel's implementation of the DR strategies may have been affected by known stressors in her life during the study and because support (i.e., feedback and in-book scripts) was not provided. It may be that a slower phasing out of support is needed for adults to be able to transfer these strategies to new contexts. However, Isabel showed marked improvement in the quality of the questions she asked. During baseline, Isabel presented many questions ($M = 9.4$) that fell out of the scope of the CROWD prompts during shared book reading, such as yes/no questions and questions that elicited a pointing response and during generalization, Isabel used the CROWD prompts more frequently than in baseline, even without scripts in the books, and used very little 'other' prompts ($M = 1.5$). Although the average number of CROWD prompts used during generalization declined from intervention, the intervention had an impact on the quality of questions Isabel used. However, the decline in this strategy and the three other strategies suggest that a more gradual decrease in support may be necessary for the intervention to have a lasting impact on participants' reading behaviors.

We also examined the effect of the use of DR strategies with fidelity on preschool aged children's expressive and receptive vocabulary related to the storybooks. Receptive and expressive scores on the individual book assessments decreased from baseline to intervention. These data suggest that exposure to DR strategies during shared-book reading with their adolescent parents does not promote children's learning of book-specific vocabulary given the design of this study. While the majority of past studies that have reported child outcomes found increases in language and/or emergent literacy skills [18], the results of the current study may have been inconsistent due to an uneven distribution of vocabulary difficulty across phases. For example, baseline vocabulary words included "dog" and "cat" while intervention vocabulary words included "librarian" and "Frisbee". Only one book was used during baseline and it was repeated five times, in comparison to four different books used during intervention that were read only twice each. This uneven distribution of complexity and increased exposure to the vocabulary during baseline may have compromised the results for research questions two and three. Another factor which may have affected the children's success on the near-transfer vocabulary task was their attention to the book during the book reading. There were many times when the children were distracted by toys in the room and wandered off during the book reading. If they did not receive repeated exposure to the vocabulary during the book reading because of distractions, their success on the vocabulary task may have been compromised. This result was unlike the positive gains in near-transfer vocabulary reported in other studies [23, 24].

Acceptance of the DR intervention was evaluated through a seven-item survey using a seven point Likert scale. Isabel reported an average score of 6.42 on the seven items,

suggesting positive acceptance of the intervention. Responses to open-ended questions aligned with this finding. In one study, Heubner [25] included adolescent mothers in the study sample and reported positive parental satisfaction of a DR intervention program. Positive satisfaction may be attributed to adolescent mothers' perceived success to implement a new strategy as opposed to feelings of nonfulfillment other areas of their life, such as school [21].

Teenage pregnancy and parenting is a multigenerational cycle including issues of low income, low academic attainment, low achievement in education, specifically in literacy, and higher risk of mental health and medical issues (see Figure 1) [4, 5, 7, 8]. We sought to address the issue at hand through one possible angle which included investigating the feasibility of using a shared reading intervention, dialogic reading, to impact an adolescent mother's reading behaviors. While this study included only one participant, we demonstrated that it is feasible to teach DR behaviors to an adolescent mother. With this data, we intend to continue in this line of research to further develop a mutually beneficial intervention, centered around literacy, for adolescent mothers and their children on a larger scale. The most successful children born to adolescent mothers are those that are read to frequently, experienced more supportive care, and had mothers who completed higher levels of education [10]. Therefore, by educating adolescent mothers on the importance of reading to their children and providing direct training on their reading behaviors, the adverse effects of early onset pregnancy may be offset and we may advance towards breaking the cycle of teenage intergenerational pregnancy.

Limitations and Future Directions

While this single case study suggests an encouraging relationship between a DR intervention and adolescent mothers' use of DR strategies, there are several limitations that must be noted. This study included only one adult participant, which may have affected the participant's learning of the strategies- whether the one-on-one attention was conducive to her learning or the lack of watching others utilize the strategies negatively impacted her learning. Future studies should obviously include a larger number of adolescent mothers. Another limitation of the current study was the uneven distribution of complexity of the book specific vocabulary across phases. The near-transfer vocabulary may have been too difficult for the age of the child participants. Another limitation was that the children were read to together, which may not have been conducive for their focus, potentially affecting the children's success on the near-transfer vocabulary assessments. Future researchers should consider participants' age range and knowledge level to choose appropriate vocabulary. Because the near-transfer vocabulary assessments measure only short-term effects, researchers may also consider analyzing the long-term effects of DR on children's oral language in facets other than vocabulary, such as mean length of utterance (MLU) and type token ratio (TTR).

Future studies should explore the minimal increases in the implementation of the expand strategy. During the expand strategy, the adult models a longer and more detailed sentence, which gives children a chance to practice longer utterances during the repeat strategy. Researchers should explore what makes this strategy more difficult to implement and what extra support is needed to implement it with fidelity. Due to the effects associated with teenage parenting, it is critical that interventions that affect adolescent mother's literacy skills

be developed. Future research should investigate the impact of implementing DR strategies during shared book reading on adolescent mothers' literacy. Developing a mutually beneficial intervention for both the mother and child is critical in breaking the intergenerational cycle that is associated with teenage pregnancy and parenting.

CONCLUSION

This study demonstrated that an adolescent mother from a low SES background was able to utilize DR strategies following a systematic training of the DR protocol. However, positive changes on children's receptive and expressive book-specific vocabulary due to implementation of DR strategies were not seen. This study contributed to the limited information that is available concerning literacy and language interventions for low income adolescent mothers and their children. Adolescent mothers' potential to effectively implement a new strategy when given the appropriate support should inspire continued research with this population. Future research must strive to understand adolescent mothers' interactions with their children in order to develop interventions that will target the areas that are lacking in order to break the multigenerational cycle seen in families of adolescent mothers.

ABSTRACT

In this chapter we evaluate the sleep characteristics of children from a low-income urban area and the barriers these children have in developing healthy sleep behaviors. A multiphase mixed-methods exploratory research design was used to provide a deeper understanding of the perceptions of parents/caregivers from low-income urban areas regarding their children's sleep. Sleep was identified as a "very important" contribution to their children's health by 97.1% of participants (options being "not important," "somewhat important," and "very important"); however, a high proportion reported a home environment that is not conducive to healthy, restful sleep. Problematic sleep habits of children, including parasomnias, sleep anxiety, and night wakening, were noted by 88.2% of the participants on the Children's Sleep Habits Questionnaire. Focus groups identified several barriers to healthy sleep hygiene practices such as television/electronics before bedtime, co-sleeping, and night waking (paired with eating/drinking). During the focus groups, many parents/caregivers reported daytime tiredness and drowsiness of their children. Discussion: Culturally-appropriate education is needed to guide parents/caregivers in creating a healthy home sleep environment. Simple measures such as removing televisions from bedrooms and discontinuing electronic use before bedtime, night waking food/beverage feeding, and co-sleeping may lead to the increased occurrence of healthy sleep with this population. Culturally-appropriate education may be

an essential element to helping this community learn strategies on creating a healthy home environment that promotes optimal sleep habits.

INTRODUCTION

The cycle of environmental health disparities in children is multifactorial and must be viewed through a health care lens which investigates and intervenes from multiple vantage points. Children from low-income communities in the United States experience greater health burdens than do those from middle- to high-income communities and are more likely to be of black race and/or Hispanic ethnicity [1]. These children are at an increased risk for asthma, infant mortality, and teen pregnancy. Upon becoming adults, these individuals are at a higher and earlier risk of hypertension, diabetes, cardiovascular disease, and stroke, the foundations for which are often established during childhood [1]. Black mothers and their children who reside in low-income areas are at highest risk for being overweight or obese [1–4]. Nationally across the U.S., 82% of black women and 55% of black children are classified as overweight, obese, or extremely obese [4]. Mobile, Alabama has the second highest obesity rates in the United States and the highest rates of adults with diabetes in the nation, tied with Charleston, West Virginia [5–7]. Despite these numbers, black women and their children are underrepresented in behavioral weight management research [5, 6, 8]. This shortage of research led the Institute of Medicine to identify obesity interventions among diverse ethnic groups as an urgent need [9].

It is important to focus on targeting modifiable risk factors such as sleep which may create an opportunity for reducing adverse health outcomes such as obesity with high risk vulnerable populations. A modifiable risk factor that can help play a role in preventing and decreasing obesity is ensuring adequate sleep for children. Poor sleep patterns contribute to obesity risk. This risk is related to identified shorter sleep duration, poor quality/less restful sleep, and increased sleep curtailment (restricting sleep time below needed amount) at an increased rate in economically disadvantaged children, black children, and Hispanic children [10]. Research has found that twenty percent of parents reported daytime fatigue in their children several days per week, and 70% report negative sleep behaviors in their children [10]. According to the age-based sleep recommendations issued by The National Sleep Foundation, preschool children should have 10-13 hours of sleep each night, and school-age children should have 9-11 hours [10]. The incidence of sleep problems is increasing at higher rates in black and Hispanic children, ranging from 25-50% [10].

Etiologies for inadequate sleep in children are dependent upon many biological, psychological, social, and environmental factors [11]. Sleep can be adversely affected by a child's temperament, neurocognitive status, and behavior. Parental contributors to sleep habits include the parents' mental health, ages, education levels, parenting styles, and sleep perceptions [10, 11]. Decreased sleep duration can be related to the failure of an individual during infancy to attain adequate self-soothing and self-regulating behaviors which initiate and maintain sleep [12]. Sleep quality and duration may also be affected by co-sleeping, delayed bedtimes, the presence of a television (TV) in the child's room, ineffective bedtime routines, and adverse dietary behaviors [10].

The detrimental psychosocial effects of poor sleep are well-documented in the literature. Children who do not sleep well are twice as likely to develop symptoms of attention-deficit

hyperactivity disorder and are three times as likely to have a conduct disorder [13]. Longer sleep has been positively correlated with improved academic performance, emotional regulation, and quality of life in children [14]. Furthermore, sleeping problems in children, including prolonged sleep latency (length of time to fall asleep) and refusal to sleep alone, were predictive of longitudinal anxiety and depression [15]. Mothers of minority children with poor sleep behaviors have also identified symptoms of depression, anxiety, and post-traumatic stress disorder in their children [16].

Research has demonstrated that poor sleep contributes to obesity. Conversely, the presence of obesity increases the incidence of obstructive sleep apnea (OSA) and other respiratory sleep disorders, circadian rhythm sleep-wake disorders, insomnia, and hypersomnolence [10, 17–21]. Thus, those who conduct sleep research, education, and interventions must consider obesity as a contributor and the outcome as well. The association between poor sleep habits and obesity is especially concerning since childhood obesity has become a severe public health concern [2]. Obesity in children is particularly prevalent in the Deep South, and black and Hispanic children of low socioeconomic status are disproportionately affected [22, 23]. Excess weight early in life increases the risk of an individual to be overweight or obese in adulthood, and Malhotra, Ostbye, Riley, and Finkelstein [24] found that, in 18 years, adults typically gained 1.2 pounds per year. Obesity in adulthood substantially increases an individual's risk for hypertension, type 2 diabetes, stroke, cardiovascular disease, osteoarthritis, and some cancers [24, 25]. The disparities found in racial and ethnic cohorts contain factors contributing to childhood obesity starting early in life [26].

The most common adverse effect of obesity on sleep is the development of OSA. The incidence of OSA in obese children exceeds 50% [27], and leads to increased sleep fragmentation resulting in daytime sleepiness and diminished physical activity, which further accelerates obesity. Sleep fragmentation from OSA also contributes to and/or exacerbates adverse cardiovascular and metabolic effects throughout the life span, such as lipid disorders and diabetes which are commonly found in individuals with obesity [25].

tolerance and sensitivity, increased evening concentrations of cortisol, changes in phospholipids, and alterations in thyroid functioning [28, 29]. One of the most marked effects of sleep disruption occurs in the hormonal processes that regulate hunger. Levels of ghrelin, a hormone that stimulates the appetite, increase in the presence of sleep deprivation. Conversely, leptin, a satiety hormone, is decreased by sleep deprivation [30]. Thus, sleep-deprived individuals experience increased feelings of hunger, particularly for carbohydrate-rich foods, and report a decreased feeling of fullness after eating [19, 20]. Also, there is an increased opportunity to snack and consume food because the individual is awake to eat.

The effects of poor sleep and obesity are far-reaching. Affected individuals are at high risk for negative health outcomes due to an unhealthy home environment. Through research and observation, it is incumbent upon healthcare providers to identify strategies to reverse negative health risk factors, including sleep disruption and obesogenic influences that contribute to the cycle of environmental health disparities.

The specific aims of this research study are to: 1) identify the sleep characteristics of children from a low-income urban area, 2) explore barriers to healthy sleep behaviors, and 3) identify the content needed for a future sleep intervention. The study was designed to investigate a component of the cycle of environmental health disparities (see Figure 1); thus,

the setting of study and recruitment of participants occurred at a child-care center located in a low-income urban area where residents experience substantial health disparities.

Figure 1. Breaking the cycle by addressing barriers to healthy sleep.

Obesogenic biochemical processes resulting from poor sleep include decreased glucose

Family members play a critical role related to the actions of each other. When parents actively participate in sleep routines and sleep hygiene, they serve as examples to their children [11]. Family Systems Theory has been used to investigate health behavior extensively and effectively [31]. The research team in the current study selected this theory to guide the understanding of sleep habits and sleep hygiene within families.

OUR STUDY

A multiphase mixed-methods exploratory research design employing concurrent and sequential phases was used to obtain data and provide context [32] and allowed for a deeper understanding of perceptions of parents/caregivers about their children's sleep. The setting of the study and recruitment of participants occurred at a child-care center located in a low-income metropolitan area where residents experience substantial health disparities. Participants were asked to complete a questionnaire (quantitative data collection) before participating in a one-hour focus group (qualitative data collection).

Quantitative Method

The Children's Sleep Habits Questionnaire (CSHQ), a validated, reliable questionnaire, was administered to parents/caregivers of children at the child-care center to identify patterns

related to the children's sleep [33]. The CSHQ is a 45-item measure of multiple sleep domains for children. The overall score of the CSHQ has demonstrated internal consistency of 41, sensitivity of 0.80, and specificity of 0.72 when used in school-age children. Evaluative subscales of the CSHQ include bedtime resistance, sleep onset delay, sleep duration, sleep anxiety, night waking, parasomnias (abnormal or unpleasant perceptions while falling asleep or waking up), sleep-disordered breathing, and daytime sleepiness [33]. The research team gained permission to use this copyrighted instrument [33].

A questionnaire (see appendix 1) was developed by the research team to obtain demographic data, bedtime routines, barriers to sleep hygiene, and dietary practices. The demographic questions included inquiry about participants' financial concerns and use of Government-sponsored programs of assistance, including Supplemental Nutrition Assistance Program and Temporary Assistance for Needy Families.

Qualitative Method

Four one-time one-hour focus groups were held at the child-care center, providing participants an opportunity to express personal experiences regarding their children's sleep practices, bedtime routines, and sleep habits. The focus group discussion was steered by a semi-structured interview guide composed by the research team with input from national experts. Upon receipt of the completed questionnaires, the research team added/adapted questions on the interview guide to further explore concepts or comments based on questionnaire responses and/or patterns as the sequential phase of the mixed-methods design.

Procedure

An expedited Institutional Review Board approval was obtained from the University of South Alabama. Parents/caregivers of children who utilize the child-care center were recruited by means of a flyer displayed in the center. The director of the center was instrumental in the recruitment and helped explain questions on the questionnaires to the participants if requested. Participants who returned the completed questionnaires were eligible to sign up for one of the focus group sessions. Completion of a questionnaire was mandatory prior to focus group session attendance to avoid bias.

The questionnaires had a waived consent with a cover sheet explaining the nature of voluntary completion. Participants who attended a focus group session consented at the beginning of the focus group. Focus groups were conducted using established methodology [34]. After consent was obtained, the sessions were audio recorded to aid in understanding and transcription. The principal investigator led each session while other members of the research team, including faculty, a graduate student, and undergraduate students, facilitated the discussion and added questions when appropriate. The investigator greeted the participants and asked the open-ended questions. A second researcher took notes of participants' comments as well as non-verbal behavior. At the end of each question, the researcher verified the discussion points, summarized responses from the discussion, and

welcomed input from participants on any missed points. Each focus group session lasted about 60 minutes.

Participants who completed the questionnaires and attended a focus group session were compensated at the end of the focus group with a \$25 gift card and were encouraged to keep all discussions confidential. Later, one researcher transcribed the recordings, and two other researchers reviewed the transcripts for accuracy. Audio recordings, notes, and transcripts were stored in a secure site.

Data Analysis

The quantitative and qualitative data were analyzed simultaneously as the concurrent phase of the mixed-methods design. Data collected from participants were cleaned and entered into a database and analyzed using SPSS v. 24. Due to the small sample size, missing data were deleted likewise. Subscale scores for the CSHQ were calculated using author-provided guidelines [33]. For this study, quantitative sample descriptive statistics, including measures of central tendency were analyzed. Additionally, scores on the CSHQ were compared using Welch's unpaired t-tests to community sample subscale scores published by Owens, Spirito and McGuinn [33] to ascertain the degree to which the current sample resembles other community samples.

Analysis of qualitative data involved examining, categorizing, tabulating, mapping, and interpreting the transcripts. The transcripts were reviewed by the research team for general themes in the discussion. The researchers identified the content and entered larger, broader themes as a distinct line item in a spreadsheet, and the items were sorted into categories. The larger categories were formed by grouping similar idea units together and then were sorted to create distinctions among them. The themes were reviewed by the researchers independently, and discussion and debate ensued until consensus was met.

OUR FINDINGS

Thirty-four participants completed the questionnaires and focus group discussions. Thirty-three participants were female, and one was male. The majority of participants (85%) were mothers of children enrolled at the child-care center. Participants were primarily black (91.2%) and non-partnered (20.6% married or partnered). The average age of participants was 32.29 years (SD 11.12). Participants varied in their levels of education, with 8.8% having less than a high-school education, 32.4% graduating from high-school/obtaining a GED, 35.3% having some college education, and 23% holding a college degree. The children of the participants had an average age of 4.43 years (SD 3.68), and 52.9% were male. When asked about perceptions of weight, more than half (53%) of the participants/caregivers answered they consider themselves to be "somewhat overweight." Almost all (91%) answered that they consider their children to be "Normal/average weight."

Household income varied widely with a mean of \$21,468 (SD \$16,711) ranging from \$5,000 to \$75,000 with a median of \$17,000; however, 12 of the participants (35%) did not answer the demographic question related to household income. When removing the outlier of

\$75,000, the mean income ($n = 21$) was \$18,919 (SD \$11,964), median was \$16,000, and the range was \$5,000 to \$50,000. The majority (58.8%) of families reported some degree of financial difficulties, and most were enrolled in Government-sponsored financial assistance programs (Supplemental Nutrition Assistance Program (SNAP) = 58.8%; Temporary Assistance for Needy Families (TANF) = 67.7%).

Participants reported on various sleep habits of their children (see table 1). Most felt that their child sleeps the right amount (67.7%), and 70.6% reported that their child “rarely” receives too little sleep. Participants reported that their children usually sleep the same amount each day (71.0%), that they felt sleep was “very important” to their children’s health (97.1%), and that bedtime routines were “very important” (88.2%).

Participants also completed the CSHQ as described above. Based on published cut-off scores [33], 88.2% of the participants indicated that their children had problematic sleep habits (Table 2). When CSHQ subscales were compared with demographic variables, a significant correlation was found between child age and daytime sleepiness ($r = .348$, $p = .044$). No other significant differences or correlations were found between the CSHQ and demographic variables.

Table 1. Children’s bedtime habits and environments (N = 34)

	n(%)		
	“Yes”	Male (n = 18)	Female (n = 16)
Child eats after bedtime	16(48.5)	7(41.2)	9(56.3)
TV on one hour before bedtime	29(85.3)	15(83.3)	14(87.5)
TV on where child sleeps	15(44.1)	6(33.3)	9(56.3)
TV in child’s room	29(85.3)	15(83.3)	14(87.5)
Child uses electronics before bed	18(52.9)	9(50)	9(56.3)
Child has own bed	30(88.2)	15(83.3)	15(93.8)
Child usually sleeps with someone else	15(44.1)	10(55.6)	5(31.3)
Child drinks caffeinated beverages	12(36.4)	7(38.9)	5(31.3)

Table 2. CSHQ subscales with comparison to the normative sample

	Mean	SD	Welch’s Unpaired t-test
Bedtime Resistance	3.12	2.81	$t(35) = 4.1911$, $p = .0002$
Sleep Onset Delay	2.59	.61	$t(37) = 12.3909$, $p < .0001$
Sleep Duration	3.94	1.37	$t(430) = 3.0553$, $p = .0024$
Sleep Anxiety	5.50	1.89	$t(36) = 1.8347$, $p = .0748$
Night Wakening	4.27	1.22	$t(36) = 3.6719$, $p = .0008$
Parasomnias	8.53	1.71	$t(36) = 1.3983$, $p = .1706$
Sleep Disordered Breathing	3.53	1.05	$t(35) = 1.5418$, $p = .1321$
Daytime Sleepiness	13.68	2.90	$t(413) = 8.0379$, $p = .0001$
Total CSHQ	48.24	7.91	$t(41) = 5.5544$, $p < .0001$

Scores on the CSHQ for the current sample were compared to the normative/non-sleep disordered sample reported by Owens et al. [33], and several significant differences were found (see table 2). Overall, the current sample reported a significantly greater disruption in sleep habits than the sample reported by Owens et al. [33].

Topics regarding current practices and barriers to healthy sleep in children that were discussed in focus groups were: 1) current bedtime sleep routines and challenges related to healthy sleep habits; 2) parent/caregiver description of restful sleep for their children and

facilitators and barriers to restful sleep; 3) effects of children's eating and physical activity behaviors related to sleep; and 4) association between the sleep and health of their children.

The focus group findings identified several major barriers to healthy bedtime sleep routines in children:

- *Electronics before bedtime:* A familiar theme that surfaced from the focus group was TV watching and/or electronic use at bedtime. One participant reported, "My baby and my child likes the noise, they just have to hear something going on." Another reported, "My daughter has to have her phone in her hand to go to sleep."
- *Co-sleeping:* Many participants reported that their children sleep with them. One participant reported, "I feel like my son just likes to have me, if he ain't got me, he won't even go to sleep, period."
- *Night waking accompanied by consumption of food/drink:* Many participants identified that their child expects/requires food or drink upon waking up during the night. The most common drinks mentioned were milk, juice, and water. Several mentioned Gatorade and Pedialyte. In terms of food during the night, several identified fruits, crackers, yogurt, jello, and leftovers.
- *Inadequate nighttime sleep resulting in daytime fatigue:* Several participants agreed with the following statements from other participants, "My children often fall asleep in the car on their way to school in the morning" and, "I often get calls from the school that my daughter fell asleep during class."

The themes, or barriers, identified in the qualitative data were echoed by findings in the quantitative data. Thus triangulation, or confirmation, was achieved through the use of the mixed-methods design.

DISCUSSION

The current research highlights the experiences and challenges faced by low-income, primarily black families related to the sleep habits of children. This study identified habits and challenges that will guide the development of interventions to help families create healthier sleep habits and make positive changes in the home environment for at-risk children. Identifying obstacles to children's sleep is critical to planning effective interventions.

Looking at children's sleep patterns among low income black families and the health and educational implications, this study identified that 97.1% of parents/caregivers identified that sleep was "very important" to their children's health. However, a high proportion reported a home environment that does not ensure restful sleep for their children. It was interesting that more than two-thirds of the parents/caregivers believe their children get enough sleep (67.7% said the child gets the right amount of sleep, and 70.6% think the child rarely gets too little sleep); however, on the CSHQ, 88.2% of the parents/caregivers identified that their children had problematic sleep habits. It appears that most parents/caregivers value the importance of sleep but may not be able to identify factors that interfere with adequate sleep quality and amounts or may not be aware of the specific sleep hygiene practices that are needed to promote healthy, restful sleep. Creating a healthy home sleep environment requires specific

strategies and interventions to ensure high-quality sleep. These findings align with previous research that children from minority, economically disadvantaged homes have decreased sleep duration, poor quality/less restful sleep, and more sleep curtailment than children who are not from minority, economically disadvantaged households [10].

The focus groups identified specific bedtime behaviors that threaten healthy sleep hygiene practices. Several themes that were reported were parents allowing electronics use consistently before bedtime, co-sleeping, and providing food and drinks upon waking during the night. The parents/caregivers also reported that children were often tired and drowsy during the day. The survey identified that many children had TVs in their bedrooms, and one of the emergent themes from the focus group indicated that the TV is frequently on before bedtime and, at times, throughout the night. This corresponds to research that identifies that these bedtime routines adversely affect healthy sleep patterns [10].

Promotion of healthy sleep with this population can play a role in preventing daytime sleepiness, a contributor to poor academic performance [14]. Healthy sleep habits can also help prevent depression, anxiety, attention-deficit hyperactivity disorders, and obesity [13]. Promoting longer sleep times can improve academic performance, emotional regulation, and quality of life in children [14].

It appears that an intervention which includes culturally-appropriate education could guide parents/caregivers on creating a healthy sleep environment to contribute to breaking the cycle of children's environmental health disparities by addressing barriers to healthy sleep [35] (Figure 1). Simple measures such as removing TVs from bedrooms and discontinuing the practices of electronic use before bedtime, night waking food and beverage consumption, and co-sleeping can lead to promoting healthy sleep with this population. Education is one of the key elements to helping this community help develop and maintain healthy sleep habits for their children.

Despite the small sample size and geographic location, this study illuminated a need for an educational intervention on healthy sleep habits and provided helpful insights about practices and barriers to healthy sleep patterns with children in a low-income urban area in the Deep South. Further research is needed in this area to validate, elucidate, and explore strategies to improve sleep practices and hygiene.

Through the current mixed-methods research design, the research team was able to become increasingly acquainted with the experiences and challenges of low-income, minority families regarding the sleep habits of children with opportunities for correlations, exploration, and increased perspective. The findings suggest that household practices supporting a more structured home environment are needed to promote healthy sleep hygiene practices with this high-risk population.

CONCLUSION

This research study identified sleep characteristics of children from a low-income urban area and explored barriers to healthy sleep behaviors. The study contributes to the understanding and appreciation of the cycle of environmental health disparities in children by highlighting the environmental factors among low-income black families relative to their children's sleep hygiene and the contribution to adverse health outcomes like obesity and its

complications. It further illuminates potential strategies and intervention research to help vulnerable populations create a healthy home environment. Promoting healthy sleep routines is an excellent starting point. Data collected during the questionnaires and focus group sessions will be used to inform future intervention research related to promoting adequate sleep.

ACKNOWLEDGMENTS

We would like to thank Ms. Tejuania Nelson-Gill, her staff, and the families for participating in this project; Dr. Judith Owens (sleep specialist at Boston Children's Hospital, professor at Harvard University) for generously allowing the use of the CSHQ for our study; Dr. Heather Hall, Interim Dean of the University of South Alabama College of Nursing, for funding this project under the Dean's Grant; and the Southeast Pediatric Environmental Health Specialty Unit (SE PEHSU) for the unique opportunity to share student research on environmental health disparities through the Break the Cycle program.

APPENDIX 1. DEMOGRAPHIC QUESTIONNAIRE

ABOUT YOUR CHILD (Child enrolled at daycare, preschool, or after-school)		
Child's Date of Birth: / /	Child's Gender: ☐ Male ☐ Female	
Child's Race: ☐ Asian ☐ Black/African American ☐ White ☐ Other (Specify)		
Child's Ethnicity: ☐ Hispanic ☐ Non-Hispanic		
ABOUT YOURSELF		
Relationship to child: ☐ Mother ☐ Grandmother ☐ Aunt ☐ Sister ☐ Other		
Your Age: _____ years	Current Zip Code: _____	
Your Race: ☐ Asian ☐ Black/African American ☐ White ☐ Other (Specify)		
Your Ethnicity: ☐ Hispanic ☐ Non-Hispanic		
Your highest grade completed: ☐ Less than high school ☐ Graduated high school/GED ☐ Some college/vocational school ☐ Graduated college/vocational school ☐ Some graduate school ☐ Completed graduate school		
YOUR RELATIONSHIP STATUS		
☐ Single ☐ Married/Partnered ☐ Separated/Divorced ☐ Other: _____		
WHAT LANGUAGE IS USUALLY SPOKEN AT HOME?		
☐ English ☐ Spanish ☐ Other (describe) _____		
PLEASE INDICATE THE TYPE OF HOME YOU LIVE IN:		
☐ House	☐ Mobile home	
☐ Apartment	☐ Condominium	
☐ Townhome	☐ Other _____	
In an average week, how many times do all of the people in your family who live with you eat dinner together? (circle one): One Two Three Four Five Six Seven		
In an average week when YOU were a child, how many times did all of the people in your family who lived with you eat dinner together? (circle one): One Two Three Four Five Six Seven		
WHAT IS YOUR CURRENT WORK STATUS?		
☐ Employed- FULL TIME	☐ Disabled, not able to work	☐ Unemployed and looking for work
☐ Employed- PART TIME	☐ Student	☐ Unemployed and not currently looking for work
☐ Retired	☐ Temporarily laid off	
DO YOU OR ANY OTHER MEMBER OF YOUR HOUSEHOLD RECEIVE ASSISTANCE FROM ANY OF THE FOLLOWING? (Please check all that apply)		
☐ Social Security/SSI	☐ Worker's Compensation	☐ Unemployment Benefits
☐ SNAP (Supplemental Nutritional Assistance)	☐ Alimony/Child Support	☐ Veteran's Benefits
	☐ Cash Assistance/TANF	☐ Other: _____
WHAT IS YOUR FAMILY'S CURRENT HOUSEHOLD YEARLY INCOME? (estimate)		
IS YOUR FAMILY CURRENTLY EXPERIENCING ANY FINANCIAL DIFFICULTIES? (Please check one)		
☐ No ☐ Some problems ☐ Many problems ☐ It is hard to meet our basic needs		
IN WHAT AREAS DO YOU HAVE FINANCIAL DIFFICULTIES? (Please check all that apply)		
☐ None ☐ Phone/Utility bills ☐ Rent/Mortgage ☐ Buying food ☐ Vehicle-related ☐ Medical		
WHO LIVES IN THE HOME WITH THE CHILD? (including you and the child)		
Number of Adults (18 years and older): _____		Number of Children (Under 18 years): _____
What is YOUR height and weight? Height: _____ feet _____ inches		Weight: _____ pounds
Do you feel YOUR weight is (circle one):		
Underweight	Normal/Average Weight	Somewhat Overweight
		Very Overweight
Do you feel YOUR CHILD'S weight is (circle one):		
Underweight	Normal/Average Weight	Somewhat Overweight
		Very Overweight

Please circle "yes" or "no" to each of the following questions

1.	Does your child have a diagnosis of ADD or ADHD?	YES	NO
2.	Does your child have behavior problems?	YES	NO
3.	Does your child have problems learning in school?	YES	NO
4.	Does your child have breathing problems during sleep?	YES	NO
4a.	If "yes" have you discussed the problem with your child's doctor?	YES	NO
5.	Does your child eat after bedtime?	YES	NO
6.	In the hour before your child's bedtime, is there a TV on near your child?	YES	NO
7.	Is the TV on all night where your child sleeps?	YES	NO
8.	Is there a TV in your child's room?	YES	NO
9.	Does your child use a cell phone, tablet, or computer before bed?	YES	NO
10.	Does your child have a bed to sleep in?	YES	NO
11.	Does your child have their own bed?	YES	NO
12.	Does your child usually sleep alone?	YES	NO
13.	Does your child usually sleep with someone else?	YES	NO
14.	Does your family have a set dinner time?	YES	NO
15.	Does your child eat dinner with the family?	YES	NO
16.	Does your child drink caffeinated soda, tea, or chocolate drink with dinner?	YES	NO
17.	Does your child drink anything besides water during the night?	YES	NO

Please circle your response to the following questions

- How important do you think sleep is to your child's health?
Not important Somewhat important Very important
- How important is a bedtime routine for your child?
Not important Somewhat important Very important
- Please rate the quietness of the place where your child sleeps:
Noisy Somewhat quiet Very quiet

Please write in your answer to the following questions

- How many hours of sleep do you think your child needs in a 24-hour period? _____
- What things help your child to sleep well?
- What things keep your child from sleeping well?
- If your child wakes up at night, what do you do to help them get back to sleep?
- When is your child's bedtime during the week on school days? _____
- When is your child's bedtime on the weekends or when out of school? _____
- How many days each week does your family eat take out or fast food for dinner? _____

Chapter 61

**THE RELATIONSHIP BETWEEN CHILDHOOD OBESITY
AND NEIGHBORHOOD FOOD ENVIRONMENT
EXPLORED THROUGH THE CONTEXT OF
GENTRIFICATION IN NEW YORK CITY**

ABSTRACT

Inequity and health disparities can be exacerbated as a result of gentrification when long-term residents are displaced, or remain but are not able to take advantage of new opportunities. The disappearance of old and emergence of new food establishments may increase the proximity to and density of healthy food options, however, affordability and consumption of healthy food, nor a decrease in risk of adverse health outcomes are not guaranteed. Our study aims to understand the relationship between gentrification, neighborhood food environment, and childhood obesity. We describe food opportunities changes in New York City using National Establishments Time Series Database stratified by gentrification status. Using data from the Columbia Center for Children's

* Corresponding Author's Email: blr2125@cumc.columbia.edu.

Environmental Health birth cohort study, we evaluate the impact of the area-level changing food chances on the body mass index z-scores of children at age five. Overall, gentrifying neighborhoods have the highest number of food chances and experience the most substantial increase in both healthy ($p < 0.001$) and unhealthy ($p < 0.001$) food chances between 1990-2010. After adjusting for covariates, higher access to healthy food chances was associated with both lower BMI z-score ($p < 0.01$) and less likelihood of being overweight or obese ($p < 0.001$) for five-year-old children. Our results suggest gentrification was associated with contemporaneous changes in the neighborhood food chances in NYC and children exposed to greater healthy foods experienced a lower probability of excess body weight by five years old. Further research is needed to understand other potential pathways connecting gentrification to childhood BMI.

INTRODUCTION

In the United States over the last five decades, the percentage of children and adolescents affected by obesity has more than tripled [1]. Nationally, nearly 1 in 5 school age children and young people (6-19 years) is obese. These trends are similar in New York City, where almost half of elementary school children and Head Start children are not at a healthy weight [2]. Obesity prevalence also impacts the very young; 1 in 5 kindergarten students, and 1 in 4 Head Start children (birth to age five), are obese [2]. Adults and children who are overweight are at increased risk for diabetes, heart disease, stroke, high blood pressure, arthritis, and some cancers [3]. Marginalized communities bear a disproportionate share of the burden of obesity and related health conditions, i.e., diabetes [4, 5]. Given that obesity begins early in life [6], childhood obesity has immediate and long-term effects on physical, social, and emotional health; the gravity of this public health issue is of great concern.

Obesity results from an imbalance of energy consumption and expenditure. The food environment provides the key ingredient in the energy equation -- the energy. The availability [5, 7-10], accessibility [11, 12] and proximity [13-15] of healthy and unhealthy food purchasing and consumption opportunities [9, 15, 16] have been associated with obesity. Also, food prices and food affordability are influential determinants of the food choices, and therefore determinants of obesity, and other metabolic chronic diseases [17-19].

The influx of investment that accompanies gentrification, reinvestment of capital, social upgrading of locale by incoming affluent groups, and landscape change, results in direct or indirect displacement of low-income groups [20]. Gentrification also brings a change in the urban food environment, affecting the access to and availability of various forms of food and beverages, grocery stores, restaurants, large big-box stores, farmer's markets, bodegas, and other food establishments [21-25]. Recent studies have indicated that shifts in the food environment in the United States (US) are transforming urban centers [11, 13, 26] from food deserts (i.e., low-income areas where a significant number of residents are located more than one mile from a supermarket) [27] to areas with abundant food options, including fresh food markets and sit-down restaurants. Breyer and colleagues report that the growing abundance of food options does not necessarily correlate with increased consumption of healthy foods for all residents. They posit that while healthy food options appear plentiful, healthy foods are economically inaccessible for socioeconomically marginalized households [28]. Healthy foods closer to home does not guarantee these healthful foods reach the tables of marginalized

residents. Breyer and colleagues [28] state this type of disconnect is most stark in gentrifying neighborhoods.

The food-related opportunities shaped by gentrification and residents' associated food choices can be described regarding the sociological concept of habitus that links structural factors to individual behavior or practices [29]. "Food habitus" can be thought of as a set of dispositions and tastes towards food that account for food and nutrition-related practices that become apparent in an individual's body, including one's weight [30]. Thus, food habitus represents the dialectical relationship between the individual's food-related choices and the opportunities afforded by the food environment. Insights to obesogenic environments can be illuminated by focusing on the interplay between the structural opportunities, or food chances (i.e., chance to purchase and consume food), that exist within the food ecology and individual-level food choices. Understanding the trends in the food environment is integral to addressing whether shifts in capital investments and shifts in the demographic composition of the neighborhood as a consequence of gentrification has an impact on the long-term health of residents.

This project focuses on the structural opportunities within New York City's (NYC) food environment. We examined associations between obesity measures of five-year-old children and 1) neighborhood healthy food chances 2) neighborhood unhealthy food chances 3) neighborhood gentrification status during 1990-2010 in NYC. Secondly, the relationship between gentrification and food chances was examined, to provide greater context to the relationship between obesity measures and the neighborhood food environment.

OUR STUDY

The project involves secondary longitudinal data analyses that integrates information from the Columbia Center for Children's Environmental Health's (CCCEH) prospective birth cohort, National Time-Series Establishments Database (NETS), New York University Furman Center, and New York City Department of Planning Community District Profiles. This work aims to evaluate the role of gentrification and food environment in the cycle of children's environmental health disparities, specifically obesity. The combination of these data sources provided the opportunity to examine how participants' neighborhood food environment influence the weight of children in the context of gentrification. The Institutional Review Board at Columbia University Medical Center approved research protocols related to CCCEH and NETS.

CCCEH has conducted a longitudinal birth cohort study beginning in 1998 that has been described extensively elsewhere [31, 32]. Briefly, CCCEH enrolled 727 women ages 18–35 years old during their third trimester of pregnancy. Women were included if they self-identified as either African American or Dominican and resided in Northern Manhattan or the South Bronx for at least one year before pregnancy. Exclusion criteria included mother's report of cigarette smoking or use of other tobacco products during pregnancy, illicit drug use, diabetes, hypertension, known HIV, or a first prenatal visit after the 20th week of gestation. Research staff abstracted medical records of mother and infant at delivery to ascertain prenatal medical history and birth outcomes. Mother-child dyads participate in follow-up visits every three months throughout the first two years and annually thereafter.

During the follow-up visit of five-year-olds, body size measurements (weight and height) were collected ($n = 486$). Children were measured in bare or stocking feet while wearing light clothing (i.e., pediatric gown, underwear, or shorts and a t-shirt). Weight was assessed using a digital scale.

A Detecto Cardinal 750 digital scale/stadiometer (Cardinal Scale Manufacturing Company) was used to collect standing height measurements until January 2010. After January 2010, CCCEH researchers assessed standing height with the Holtain-Harpenden Wall Mounted Stadiometer Counter 602VR (Holtain Limited). Body mass index z-scores (BMIZ) were quantified using the SAS programs provided by the CDC [33]. According to the CDC child growth charts, the overweight category is defined as BMI 85th to less than the 95th percentile while obese is defined as 95th percentile or greater for age and sex. The mothers' weight before pregnancy was self-reported during the third trimester.

New York City Food Environment and Gentrification

The NETS database (Dun and Bradstreet data from January of each year to create an annual census of businesses and many nonprofit and government agencies) [34-36] was used to develop a food environment measure for each sub-borough areas (SBA; geographical unit similar to community district) in NYC for each year from 1990-2010. Kaufman and colleagues [37] recently analyzed NETS to measure health-relevant business over the same 21-year time span in the NYC metropolitan area. Of the 25 categories defined by the research team, 13 relate to food establishments. Aggregate level data for unhealthy and healthy food chances are the central interest in our analyses. Unhealthy food chances are defined as fast food restaurants, pizza restaurants, bakeries and candy/confectionary stores, meat markets, and corner store/deli often described as “bodegas.” Convenience stores were not included in the aggregate measure because corner stores represent this category in NYC. Healthy food chances are defined as fruit and vegetable markets, natural food markets and nut stores, fish markets, small grocery stores, and large supermarkets. Our analyses operationalized the food environment by the average food chances per square kilometer. To increase accuracy, bodies of water are excluded from the area of the neighborhoods.

Second, we used the Furman Center of New York University [38] gentrification classification system to measure gentrification status of NYC's neighborhoods during the same period that food chances were estimated (1990-2010). In brief, the criteria defining the classification systems relate to the median income of the neighborhood in 1990 and the median rent growth between 1990-2014. NYC is comprised of 55 SBAs. “Gentrifying” neighborhoods consist of SBAs that meet two criteria: 1) low-income in 1990 and 2) experienced rent growth above the median SBA rent growth between 1990 and 2014. “Did not gentrify” neighborhoods also started as low-income in 1990 but experienced no growth or more modest rent growth. “Not eligible to gentrify” neighborhoods” are the city's remaining SBA, which had higher incomes in 1990.

Primary Analyses

We aimed to understand the relationship between childhood obesity and the changing food environment of children in the context of gentrification. This overall analysis required evaluation the several relationships including a) food chances, time and gentrification status; b) obesity and food chances trajectories c) obesity and gentrification. Below we provide details of these three analyses conducted.

To assess how food chances change throughout the 21-year timeframe, we conducted group-based trajectory model estimation (GBTM) on the number of food chances in the SBAs where CCCEH children lived at age five during 1990-2010. GBTM models the number of food chances as a continuous function of time (measured annually) and estimates the probability of trajectory membership for each food category. GBTM was conducted on healthy and unhealthy food chances separately to generate specific trajectories for each category. We log-transformed the count of food chances to better approximate a normal distribution and estimated models with varying numbers of groups [1–6] and shapes (linear, quadratic, cubic). We evaluated model fit using the Bayesian Information Criterion (BIC), as well as the magnitude of group membership posterior probabilities. The relationship between food trajectories and gentrification status (gentrifying, did not gentrify, and not eligible to gentrify) was assessed using chi-square Fisher Exact tests. The analyses GBTM were performed using the Stata command “traj” developed by Bobby L Jones and Daniel S Nagin [39]. Table 1 provides the number of groups, shape, and BIC for both healthy and unhealthy food chance trajectories.

Table 1. Food chances trajectories according to the number of groups, shapes, and BIC

Food Chances Category	Number of groups	Trajectory shapes ¹	BIC ² (N = 24)
Healthy Food Chances	2	1 1	1.1
	2	1 2	8.3
	2	2 1	10.3
	2	2 2	17.9
	2	3 3	24.7
	2	4 4	32.5
Unhealthy Food Chances	2	4 4	-26.9
	3	1 1 4	26.6
	2	4 1	-30.5
	3	1 1 4	51.66
	2	1 4	-53.1

¹ Trajectory shapes: 1 = linear; 2 = quadratic; 3 = cubic; 4 = quartic.
² BIC = Bayesian information criterion (for the total number of Sub-boroughs).
* One or more of the groups had a very small proportion of the observations.
* The food ecology is described concerning food chances to reflect the sociological construct of habitus that provides insights to obesogenic environments by focusing on the interplay between food chances and food choices. Food chances are the food establishments available in a neighborhood.

The relationship between obesity and the previously calculated trajectories were examined through linear regression of BMI z-scores and logistic regression of overweight/obesity status based on the CDC classification [33] of five-year-old children. Given that enrollment for CCCEH occurred from 1998-2006, children reached age five between 2003-2011. This period falls within the years covered by the NETS dataset and the

Furman Center's gentrification classification of NYC neighborhoods (199-2010). CCCEH participants turned five-years-old between 2003 and 2011. This period is one year beyond the period covered by NETS and the Furman Center. For those children that turned five in 2011 ($n = 26$), the food chance trajectories experienced in 2010 were included in the study.

Fisher Exact tests were conducted between the binary variable of overweight/obese status and gentrification status. Similar to the previous analysis, the relationship between obesity and gentrification was assessed through linear regression of BMI z-scores and logistic regression of overweight/obesity status as the dependent variables and the gentrification status of the child's SBA.

Three adjustment strategies were considered for each of the aforementioned linear and logistic regressions: univariate model, individual-level only model, and full model with both individual and area-level covariates. Individual-level covariates include children's age, gender, race/ethnicity (African American or Dominican American), mother's pre-pregnancy BMI, mother's years of education, and use of public assistance at least once from the period during pregnancy through the child being five-years-old. Area-level covariates include SBA average population size between 1990-2010, the land area of SBAs (square km, excluding bodies of water), percent of households with SNAP benefits in the past 12 months, and percent of residents with less than high school diploma. The population size was derived from the United States Census Bureau decennial census; the American Community Survey data (2006-2010 5-year estimates) was the source of all remaining area-level covariates.

Contextual Analyses

To graph changes in the food environment of CCCEH participants over time, we used locally weighted scatterplot smoothing (lowess) on the NETS data for the SBA in which CCCEH participants resided while the child was five-years-old. Lowess bandwidth of 0.4 was used to provide locally weighted scatterplot smoothing that narrowly followed the data. CCCEH participants with completed data on all variables of interests (BMI z-scores, BMI percentile, neighborhood, child's gender, child's age, child's ethnicity, maternal education, pre-pregnancy BMI, and use of public assistance) reside in 24 of NYC's 55 SBAs. Thus, only these 24 SBAs were used in the lowess plots to capture the food environment that CCCEH participants experienced. Figures 1 and 2 display the average number of food chances per square kilometer stratified by the gentrification status from 1990 to 2010.

Software

We performed all statistical analyses with Stata version 15 and graphics were developed with grystyle software [40]. All regression analyses used cluster-robust standard errors to account for participants clustering within SBAs.

FINDINGS

The sample included 486 mother-child pairs from CCCEH with 54% female children. The majority of participants self-identified as Dominican, obtained at a least high school diploma (or GED) and never received public assistance before or while the child was five years old. Mothers’ pre-pregnancy BMI places nearly half as overweight or obese before pregnancy. At age five years, children predominantly lived in gentrifying neighborhoods and over a third of the sample of children were overweight or obese. Table 2 provides demographic information about the CCCEH mother-child dyads.

Trajectory Analyses of Food Chances

GBTM of unhealthy and healthy food chances in CCCEH SBAs result in models with two trajectory groups that follow parallel increasing slopes (see Figures 1 and 2). The trajectories for healthy food chances were best fit with a linear term function of time and the trajectories for unhealthy food chances were best fit with a more complex model that requires a quadratic function of time. Results of these analyses are provided in Table 1. The food chances trajectories are classified as either low or high access. However, it should be recognized that the “low” and “high” descriptors are relative to the type of food chances category and lack an equivalent numeric representation. In other words, SBAs classified as “high access” to healthy foods is not equivalent to the number of food chances available in “high access” unhealthy food SBAs.

* The food ecology is described concerning food chances to reflect the sociological construct of habitus that provides insights to obesogenic environments by focusing on the interplay between food chances and food choices. Food chances are the food establishments available in a neighborhood.

* (p < .05) ** (p < 0.01) *** (p < 0.001).

The range for healthy food chances per square kilometer is between 2 and 7; while the range for unhealthy food chances is 8 to 54, indicating that it is more likely, in any SBA, that an individual will come in contact with an unhealthy vs healthy food outlet. This indicates that within an SBA, it is far more likely that an individual will interact with an unhealthy food establishment vs. a healthy food establishment. The healthy food chances GBTM suggests that 63% of SBAs where CCCEH participants resided during 1990-2010 were low access healthy food chances trajectories, while the remaining neighborhoods are classified as high access. GBTM of unhealthy food chances found 75% of SBAs contain low access trajectories.

Gentrification Status and Trajectories of Food Chances

In the CCCEH sample, the majority of households resided in gentrifying SBAs (see Table 3). Nearly a quarter of the participants resided in SBAs that did not gentrify between 1990-2010. These SBAs that did not gentrify only include the low access trajectories of healthy and unhealthy food chances. Only 27 participants resided in SBAs not eligible to gentrify. Low access to unhealthy foods is more common in SBAs that are not eligible to gentrify. There are statistically significant ($p < 0.001$) differences between gentrification status and unhealthy and healthy food chances trajectories.

Regression Analyses of Children's BMI and Food Chances Trajectories

We analyzed the relationship between children's BMI z-score and food chances GBTM. Across all models, children residing in neighborhoods with high access to healthy foods have lower BMI-z scores and less likely to be overweight or obese compared to children who resided in neighborhoods with low access to healthy foods (see Table 4). BMI-z is significantly lower in adjusted models at the individual level (beta = -0.32; 95% CI: 0.5, -0.1).

Children are less likely to be overweight or obese controlling for individual and area-level covariates respectively (OR = 0.58; 95% CI: 0.4, 0.8; OR = 0.35; 95% CI: 0.2, 0.8). Across all models, children residing in neighborhoods with high access to unhealthy food chances trajectories had slightly lower BMI-z scores. The logistic regression model predicting overweight or obesity adjusted for individual-level covariates was significant (OR = 0.68; 95% CI: 0.5, 1.0).

Regression Analyses of Children's BMI and Gentrification Status

The majority of children in the study are not overweight or obese (n = 299), and 71% of them live in gentrifying neighborhoods. A small percentage (5%) of healthy weight children reside in SBAs not eligible to gentrify and the, remaining 24% lived in SBAs that did not gentrify during 1990-2010. Similar to their healthy counterparts, overweight or obese children (n = 187) primarily live in gentrifying SBAs (65%), a small percentage live in SBAs not eligible to (6%), and a slightly higher percentage live in SBAs that did not gentrify (29%). There are no statistically significant differences between these groups (see Table 5).

Table 5. Overweight/obese status and gentrification status among CCCEH participants at age five

Exposure	Gentrifying	Did not gentrify	Not eligible to gentrify	Total	P> z Fisher's Exact Test
Neither overweight nor obese	211 (70.57 %)	73 (24.41 %)	15 (5.02 %)	299	
Overweight or obese	121 (64.71 %)	54 (28.88%)	12 (6.42 %)	187	
Total	332 (68.31%)	127 (26.13%)	27 (5.56%)	486	0.386

SBA that did not gentrify (as compared with gentrifying neighborhoods) were associated with higher BMI z-scores. However, this was only statistically significant in the unadjusted model (beta= 0.18; CI: 0.0, 0.3). This positive relationship was also present in the logistic regression analyses of overweight or obesity status but also lacked statistical significance. SBAs not eligible to gentrify (as compared with gentrifying neighborhoods) were also associated with higher BMI z-scores and being overweight or obese, but also lacked statistical significance. Full details are presented in Table 6.

Food Chances and Gentrification Status

The SBAs where CCCEH participants resided, food chances increase over time, across all categories of gentrification, there seems to be a surge in food chances around 1995, with a steady increase from 2000 until 2008 where the number of food chances declines (see Figure 3). This pattern is present in all three categories of food chances; however, the sum, mean and range vary between healthy and unhealthy food chances (see Figures 4 and 5).

Gentrifying SBAs have the most food chances across all years, (mean = 49.4; median = 47.8; range = 17.7-104.4). SBAs that did not gentrify followed (mean = 68.2; median = 57.4; range = 14.9 -253.1). SBAs not eligible to gentrify offered the lowest number of food chances per square kilometer during 1990-2010 (mean = 26.1; median = 24; range = 5.2-70.5).

n = Neighborhoods defined by NYC sub-borough areas.

* Area of neighborhood excludes bodies of water.

** The food ecology is described concerning food chances to reflect the sociological construct of habitus that provides insights to obesogenic environments by focusing on the interplay between food chances and food choices. Food chances are the food establishments available in a neighborhood.

Figure 4. Average healthy food chances available to Columbia Center for Children's Environmental Health participants categorized by gentrification status during 1990-2010.

Overall there are fewer healthy food chances than unhealthy food chances available to CCCEH participants across all years and gentrification categories. Gentrifying SBAs have both the greatest number of healthy (mean = 6; median = 5.5; range = 1.2-14.9), and unhealthy (mean = 36.7; median = 31.7; range = 9.1-93.2) food chances across all years. Food chances afforded by SBAs that did not gentrify had fewer healthy (mean = 4.1; median = 4.1; range = 1.7 -7.9) and unhealthy (mean = 30.2; median = 26.9; range = 9.6-68.1) food chances are less than gentrifying SBAs. SBAs not eligible to gentrify offered the lowest number of food chances per square kilometer for both healthy (mean = 2.7; median = 2.7; range = 0.4-5.7) and unhealthy (mean = 13.5; median = 12.1; range = 2.1-35.7) food chances.

n = Neighborhoods defined by NYC sub-borough areas.

* Area of neighborhood excludes bodies of water.

** The food ecology is described concerning food chances to reflect the sociological construct of habitus that provides insights to obesogenic environments by focusing on the interplay between food chances and food choices. Food chances are the food establishments available in a neighborhood.

Figure 5. Average unhealthy food chances available to Columbia Center for Children's Environmental Health participants categorized by gentrification status during 1990-2010.

DISCUSSION

This study evaluated shifts in food chances as a function of gentrification, and the relationship between area-level healthy and unhealthy food chances and the BMI of five-year-old children in a birth cohort study. An increase in food chances was noted between 1990-2010. Gentrifying neighborhoods experienced the most significant increase of opportunities to purchase foods, including both healthy and unhealthy food chances, and participants living in areas that were not eligible to gentrify experienced lower availability of healthy and unhealthy food sources throughout the time period. Greater area-level availability of healthy foods was associated with lower BMI at age five. Although unhealthy food sources were more abundant, there was no observed relationship between area-level availability of unhealthy foods and excess weight in this sample. While most of the birth cohort sample lived in areas classified as gentrifying, there was no statistically significant association of area-level gentrification with BMI at age five.

Changes in urban food ecology as a function of gentrification have not only taken hold in New York City but across the nation. Our findings provide insights to study the effect of gentrification on health retrospectively. Despite the lack of a universally accepted operational definition, gentrification connotes images of a capital investment that often create a flourishing food ecology. For instance, communities defined as food deserts are transformed into an abundance of food opportunities. Some researchers are not convinced that these new establishments will transfer into actual uptake of healthier food consumption [28, 41]. We

hypothesized that gentrification would increase healthier food chances. The NETS data indicate that there was an overall increase in food chances throughout the city regardless of gentrification status, including an overall increase in healthy food chances in gentrifying neighborhoods until 2008. However, gentrifying neighborhoods held not only the greatest abundance of healthy food chances but also the greatest abundance of unhealthy food chances. The simultaneous increase suggests that all food chances are increasing, but there are more opportunities to choose unhealthy options. In terms of food habitus, residents may lean towards what is more available, accessible, and affordable to obtain in their neighborhoods. The food habitus formed by the historic lack of healthy foods chances will take time to change, even when healthy foods become available and affordable.

Moreover, a change in habitus does not occur immediately. Thus, lasting dispositions towards one's food choices may remain. Residents that have formed a less health-promoting food habitus due to a past absence of healthy food chances could be more susceptible to continuing to choose the unhealthy options that are becoming increasingly available in their neighborhood.

Given the literature on the abundance of fast food outlets in marginalized communities [27, 42-46], it was surprising that gentrifying SBAs experienced more of an increase in unhealthy food chances as compared with SBAs that did not gentrify. This may be a result of overall growth and opportunities for capital investment of food businesses signaling broader changes to the retail ecology irrespective of healthfulness. Lastly, it should be noted that we believe the decline near the end of our observation period and across all gentrification statuses may be a result of the 2008 economic crisis as well as trends toward more online food retail.

The two trajectories identified by the GBTM analyses for healthy and unhealthy food chances resemble the lowess curves for both of these categories confirming the latter analyses. The significant relationships between a) gentrification status and food chances and b) healthy food chance trajectories and obesity would suggest an association between gentrification status and obesity. However, this was not detectable, and future investigations may provide insight as to whether such an association would be observed with sufficient statistical power and variation in the environment. It is clear that the process of gentrification may influence the food ecology, and a food environment higher in availability healthy foods may be protective against children developing obesity. The relationship between gentrification and childhood obesity, and the causal nature of links along this pathway, would benefit from further research.

The lack of association between increased access to unhealthy foods and obesity is contrary to public discourse about the association between fast-food outlets and BMI. Yet, this finding is consistent with prior work in NYC [47]. The ubiquitous nature of bodegas, fast food restaurants, and other unhealthy food chances in NYC may have oversaturated the environment such that healthy food access is more of a limiting factor, constraining food choices of CCCEH participants.

Availability of healthy foods as measured in this study is only one of many factors that play into household food purchases. If household food purchases are determined largely by cost, there may be a preference toward familiar, less expensive foods, limiting the risk of dissatisfaction and potential food waste. Moreover, highly processed foods are less likely to be wasted due to perishability. As previously mentioned, habitus takes time to change therefore an expanded time frame for future research efforts to capture potential changes in habitus is needed.

* The food ecology is described concerning food chances to reflect the sociological construct of habitus that provides insights to obesogenic environments by focusing on the interplay between food chances and food choices. Food chances are the food establishments available in a neighborhood.

Figure 6. Breaking the cycle of children's obesity and environmental health disparities.

Beyond the household, it is important to consider policy-related influences from our community and government on children who are five-years-old. In our sample, 17% of families received public assistance at least once during the time of this study. Some programs, i.e., the Women, Infants, and Children (WIC) only benefit families until the child's fifth birthday. Thus, nutritional intake may suffer once no longer eligible. Further research beyond the age of five can provide more insights to the impact of aging out of WIC. Also, children of this age may participate in meals provided by his or her public school; as many as, two meals and one snack per school day. United States public school meal programs are notoriously underfunded and often provided ultra-processed foods. Food choices of under-resourced families become limited while a child's palate adapts to a constrained menu. Gentrification may exacerbate the lack of resources for local public schools in the most economically disadvantaged areas, and increase segregation as a result of the decision not to attend local schools in which children are assigned. [48, 49]. Currently, 40 percent of NYC kindergartners do not attend his or her assigned school; leading to concentrated poverty in zoned schools [49].

There are several limitations to this study that should be acknowledged. First, the sample is limited to less than half of NYC neighborhoods and a specific cohort associated with CCCEH. A city-wide sample and better yet, a national sample would provide a better representation of gentrification in the United States. Secondly, the complexity associated with measuring gentrification limits our understanding of the multifaceted social process. Using the Furman Center's definition relies on the assumption that gentrification can be distilled to a simple categorical variable for the entire time period rather than varying in intensity and dynamic over time. There may be nuances or levels of gentrification that change the status of

a neighborhood during the period of study. Future analyses may consider creating a continuum measure of gentrification that is informed by input from community residents.

Moreover, food chances categories may not have been able to capture gradations within the food environment. For example, food chances labeled as “healthy” may offer “unhealthy” items (e.g., candy at a supermarket) and vice versa (e.g., apple slices or salads at fast food restaurants). Also, there may be differences in the food choices made by individuals shopping and eating at these food establishments, such that our categorization oversimplifies the multi-faceted nature of variation in the food environment. As previously mentioned, including an investigation of food habitus (the interplay between food chances and food choices) can provide useful insights for understanding food practices and reducing disparities in childhood obesity. We were limited to data collected during CCCEH follow-up visits that did not capture household food choices or diet quality.

Despite these limitations, this study had substantial strengths. The multiple sources of data coalesced to provide a multi-faceted picture of the food environment experienced by CCCEH five-year-old children. The longitudinal nature of the NETS data allowed for the food environment changes associated with the social process of gentrification to be captured over time. As a single measure of food availability is unlikely to describe the food environment, we were able to measure both unhealthy and unhealthy food chances for 21 years. Lastly, we applied GBTM, enabling the identification food chance trajectories that provided an empirical basis for identifying and describing groups.

CONCLUSION

Our results suggest gentrification influences neighborhood food environment in NYC and children exposed to plentiful food chances as well as greater healthy foods experienced a lower body mass index by age five. The interplay between obesogenic food chances and choices is integral to preventing childhood obesity. Figure 6 provides a visual representation of how our work builds on a foundation of children’s environmental health research that aims to reduce inequities. Further research is needed to understand the pathways through which gentrification impacts childhood obesity and to inform policy and community actions that can break the cycle of childhood obesity in minoritized populations.

ACKNOWLEDGMENTS

We want to acknowledge the support of the Break the Cycle of Children’s Environmental Health program that provided an opportunity to bring this project into fruition. Also, we appreciate the mothers, children, and research staff of CCCEH as well as the helpful feedback, patience, and insights of Jesse Cahill, Whitney Cowell, Lori Hoepner, Bobby Jones, Helen-Maria Lekas, and Leslie Rubin.

Chapter 62

**RELATIONSHIP BETWEEN COMMUNITY
CHARACTERISTICS AND SCHOOL ENGAGEMENT
AMONG UNITED STATES CHILDREN,
NATIONAL SURVEY OF CHILDREN'S HEALTH,
2011–2012**

Breyanna M. Mikel*

Department of Epidemiology, School of Public Health, Georgia State University,
Atlanta, Georgia, USA

ABSTRACT

Neighborhood conditions and the built environment are social determinants and influences for various health outcomes – including chronic diseases, such as heart disease and obesity. However, there is limited information about how the specific structural aspects of the built environment have an impact on educational outcomes among school-aged youth. This chapter provides insight into this area by examining the association between the presence of school amenities and school engagement among children 6-17 years of age in the United States. Data from the 2011-2012 National Survey of Children's Health were analyzed. Bivariate and chi square analyses were conducted to analyze the affect that community amenities have on school engagement among school-aged youth across the United States. The results showed that children living in communities with at least one amenity in their neighborhood (i.e., recreation or community center, library, sidewalks) were more likely to have higher levels of school engagement (OR = 1.37; 95% CI = 1.24-1.52). Findings revealed that males (2.31, 2.20-2.40), youth in middle and high school (1.77; 1.69-1.85), and non-Hispanic Black students (1.15; 1.07-1.23) have increased likelihoods of having lower school engagement. Further, the findings from this study indicate and highlight the significance of identifying subgroups and demographics of youth with low school engagement living in communities lacking amenities to help build academic engagement.

INTRODUCTION

With education strategies constantly evolving and the rigor of the curriculum increasing, students across the United States face growing challenges and responsibility within the classroom. Aside from the textbook lessons that students work on, there is an increased focus on a more holistic education that includes the development of various skills through social interactions and activities. Outside of the classroom, schools and other youth-centered institutions offer additional organizations, clubs, and activities for students to participate in and create a positive environment for students in which to flourish. These strategies cumulatively contribute to establish a concept of school engagement among school-aged youth.

The concept of school engagement, also referred to as student engagement, is one that includes:

- a student's participation in school and extracurricular activities
- the emotions, motivation, attention, and effort demonstrated by students
- the way that students identify themselves within the hierarchical setting of school [1].

Specifically, the definition of school engagement consists of students having meaningful involvement and learning experiences in an academic environment. School engagement encompasses various levels of involvement from the student – including, emotional, behavioral, and cognitive – and is considered to be multidimensional [1-3]. Moreover, school engagement is manifest when students actively participate and identify with the school and the school community resulting in positive outcomes from the student [1]. School engagement is operationalized through academic success, active participation, and awareness on multiple levels by the student. There is a connection and relationship established and maintained by the student with other prominent players related to the school environment – such as the parents, the teachers, the administration, the peer network, and the community.

School engagement is a significant precursor to of school and academic success among youth. There is evidence in the literature that decreased school engagement threatens educational and professional success. Specifically, it contributes to growing dropout rates, poverty, limited employment opportunities, and crime. There are various determinants that influence school engagement among school-aged youth. Previous research by Quin et al. [4], provides an ecological framework to identify potential correlates impacting school engagement – also referred to as academic engagement in the literature – which focuses on the individual, family, peer, school, and community levels [4]. When utilizing the ecological framework as a guide, the individual level includes inter- and intrapersonal factors, such as genetic factors, personal attitudes and belief systems, and lived experiences as determinants of school engagement. Examples of this include participating in extracurricular activities, and personal involvement, motivation, and interest as well as such negative elements such as truancy and absences. Additionally, the student's gender, age, grade level, overall health and well-being plays a significant role in the student's school engagement. As part of the student's individual level of school engagement in the ecological framework, is the influence of family. Students who come from households where the parent/guardian plays an active role in the child's academic success are likely to have increased school engagement [5].

Moreover, as students get older and advance in their grade level their peer group and social network posit into the overall trend in decreased school engagement. Finally, the school level focuses primarily on the teacher's support, while the community level fundamentally accounts for how students feel about the community that they reside in.

Figure 1. Diagram of how limited neighborhood amenities acts a determinant.

Additional community and/or neighborhood characteristics have not been used in previous literature to determine whether they had some influence on school engagement. Community and neighborhood level issues do result in individual level outcomes and performances ranging from chronic diseases (i.e., heart disease and obesity) to behavioral and mental health (i.e., depression and posttraumatic stress disorder) [9]. With community disarray and disorder present, individuals, specifically, youth, living in neighborhoods with dilapidated buildings, inadequate amenities, crime, and poverty have an increased likelihood of having delayed development socially, emotionally, and cognitively – all of which impact academic outcomes [10]. This is contextualized through the poem entitled “‘Cause I ain’t got a pencil”, which depicts the domino effect of living in a neighborhood with limited resources and/or residing in a community in disarray (see Figure 2).

In the ecological model, individual contexts had the greatest influence among school engagement [4]; however, when analyzing community level influence, only two characteristics were analyzed: low attachment and disorganization. Based on the Quin, et al. [4] study, the characteristic of disorganization is one that consists of the presence of dilapidated housing, which is a variable used in our current study. While the literature

surrounding the built environment and neighborhood amenities influencing school engagement and other academic outcomes is limited, there is research about poverty, violence, and community relationships as they serve as an attribute of neighborhood amenities [11, 12].

Figure 2. “Cause I ain’t got a pencil” by Joshua T. Dickerson.

Specifically, Galster et al. [5], conducted a study on how various neighborhood characteristics, including the presence of community violence and environmental pollution (e.g., ambient noise and presence of lead,) operate through intermediate variables that result in decreased school engagement, such as school absences and trancies [5]. Additionally, Sastry and Pebley [6] posited that aside from the school environment, students spend most of their time in their respective neighborhoods and communities. Because of this, there is concern that the socioeconomic inequalities present in poor and disorganized neighborhoods have an impact that widens the achievement gap and contribute to educational health disparities [6, 7]. Furthermore, researchers have studied the importance of a neighborhood’s social and cultural characteristics on both academic engagement and success. This is measured through the social capital and interactions present in the neighborhood and its residents. Those neighborhoods with stronger social networks and cohesion result in a culture that fosters security, resiliency, and overall success among youth in an academic setting [8].

Due to the alarming trends surrounding school engagement and the limited literature dedicated solely to the built environment of neighborhoods, it is important to analyze the relationship between the built neighborhood amenities and school engagement. The focus on the built environment – particularly, the presence of community amenities – is important because it addresses the toxic cycle that continues to plague and perpetuate poor communities across the United States. Neighborhoods with dilapidated conditions lacking community amenities are at increased risk for crime, community violence, and community trauma (see Figure 1). Those negative characteristics have a direct negative effect on school attendance, academic success, and academic engagement. Students who do not feel a sense of belonging at their schools have a greater likelihood of not completing high school, engaging in crime, and/or participating in other risky behaviors. Ultimately, these three outcomes are gateways to

limited educational and employment opportunities and incarceration. Overall, the burden on the community increases due to the limited social capital and resources that need to be invested in neighborhoods with poverty and crime. We hypothesize that school engagement decreases when school-aged youth are exposed to negative structural elements of the community and low neighborhood amenities that potentially diminish and devalue a community.

OUR STUDY

We analyzed data from the 2011–2012 National Survey of Children’s Health (NSCH). The NSCH employs a cross-sectional sampling design and uses random digit dialing and telephone surveys to collect detailed information from households with at least one child, on topics related to health and well-being, community amenities and school activities, and medical coverage [13]. From each eligible household, one child was randomly selected to be the subject of the survey and the parent or guardian that has knowledge of that child’s health completed the survey. The complete description of the 2011–2012 survey is available at <http://www.cdc.gov/nchs/slait/nsch.htm> [13]. Because the NSCH is a public data set, institutional review board (IRB) approval was not required for this analysis.

Sample

The overall NSCH sample consisted of 95,677 children ranging from the ages of 0 to 17 years ($M = 8.85$, $SD = 5.23$), 51.6% of participants were male, while 48.4% were female. For the purpose of this analysis, only data on children between 6 and 17 years of age were used because the children 5 years of age and have not been in a school setting long enough to gauge academic performance ($N = 59,192$; $M = 11.16$, $SD = 3.18$).

Dependent Variable

The outcomes of interest for this analysis are: a. child cares about doing well in school and b. child completes all required homework. At the time of data collection, parents were asked to report whether their child cared about performing well in school (never, rarely, sometimes, usually, always) and completed all required homework in the previous month (never, rarely, sometimes, usually, always). Together, these variables comprise the NSCH child health indicator of “school engagement”. For the purpose of this analysis, each variable was dichotomized into either rarely (never, rarely, or sometimes) or often (usually or always).

Independent Variables

Sociodemographic characteristics. Individual-level sociodemographic covariates included race/ethnicity (white, black, Hispanic, other), sex (male, female), and age (6–11, 12–17

years). We were also interested in family-level sociodemographic covariates, including household income based upon the federal poverty level (<100%, 100–199%, 200–399%, and >400%) and family structure. Categories for family structure included two-parent household (two biological or adopted parents), two-parent household—step (two-parent household with at least one step parent), single mother (one parent household with biological, step, foster, or adoptive mother and no father), and “other”.

Neighborhood characteristics. For this analysis, we were primarily interested in the presence of neighborhood amenities and detracting neighborhood elements. The NSCH identifies both the presence of neighborhood amenities and the presence of detracting neighborhood characteristics as child health indicators. We defined presence of neighborhood amenities by affirmative answers to three or more of the following questions: 1) Do sidewalks or walking paths exist in your neighborhood?; 2) Does a park or playground area exist in your neighborhood; 3) Does a recreation center, community center, or boys’ or girls’ club exist in your neighborhood and 4) Does a library or bookmobile exist in your neighborhood?

We defined presence of detracting neighborhood elements by affirmative answers to at least one of the following questions: 1) In your neighborhood, is there litter or garbage on the street or sidewalk? 2) How about poorly kept or rundown housing? or 3) How about vandalism such as broken windows or graffiti?

Analysis

We used SAS 9.4 to conduct a secondary analysis of the 2011–2012 National Survey of Children’s Health dataset. We conducted Wald’s chi square tests and bivariate analyses to provide descriptive statistics and determine the association between school engagement and the various sociodemographic variables. We calculated crude and adjusted odds ratios (ORs) and 95% CI to examine the association between the presence of neighborhood characteristics and school engagement. Children whose parents reported that their child usually or always cared about doing well in school and completed all required homework served as the referent group, respectively. Logistic regression models were built separately for the presence of neighborhood amenities and the presence of detracting neighborhood elements to calculate odds ratios.

FINDINGS

The majority of the sample of 6 to 17 year old children were non-Hispanic White (66.8%), followed by Hispanic (12.9%), non-Hispanic Black/African-American (9.7%), with Multi-racial/Other, non-Hispanic (10.6%) making up the rest of the sample. Table 1 shows the number and percentages of children with various sociodemographic and neighborhood characteristics in 2011–2012 as well as the odds ratios comparing those with no or low school engagement and those with moderate or high school engagement. There was a higher prevalence of children who come from a two-parent household with an income more than 400% above the FPL and living in neighborhoods with a high presence of amenities.

We analyzed the association between the two components of school engagement – cares about school and completes all homework – using chi-square tests (see Table 2). Table 1 provides the odds ratios for the components of school engagement and the covariates that were included in the model, while Table 2 highlights the presence of community amenities – or lack thereof. When we analyzed the 2011-2012 NSCH, we found an adjusted odds ratio of 0.92 (95% CI = 0.89-0.93) for children caring about school and living in a neighborhood with at least one detracting element. Further, for youth living in neighborhoods with at least one amenity present, they were 1.37 (95% CI = 1.24-1.52) more times to have high school engagement compared to their counterparts living in neighborhoods with detracting community elements. Finally, when analyzing covariates, several yielded significant findings, including males (2.31; 2.20-2.40), non-Hispanic Blacks (1.15; 1.07-1.23), middle and high school-aged students (1.77; 1.69-1.85), having any poverty level greater than 100%, and having a family structure other than two-parent biological (see Table 1).

Table 1. Characteristics of youth and bivariate association with school engagement and without school engagement

Participant Characteristics	No/Low School Engagement N = 10,778	School Engagement N = 48,488	OR (95% CI)
N = 59,266			
Age, years Median (IQR)	12 (10-15)	11 (8-14)	
Sex			
Male	7261 (67.4)	23298 (48.1)	2.31 (2.20, 2.40)

DISCUSSION

Within the NSCH, the variable school engagement is a proxy for academic success. Both academic success and the level of school engagement can be influenced by both individual level and community level determinants. Neighborhood amenities act as a protective factor for the two components that make up school engagement – student cares about school and student completes required homework. Despite the results indicating that there is a statistical significance among all variables – with the exception of race/ethnicity and presence of neighborhood amenities - there was very little difference between the two groups. However, the variable of sex of the student was the only significantly different result that did not include 1 within the confidence interval.

In order to address community disorder and amenities, there is a need for bottom-up, rather than top-down, policy and interventions to obtain qualitative and quantitative data from

the communities. There is a need to create buy-in and ensure that residents of communities and neighborhoods with limited amenities are interested stakeholders with a seat at the table. Moreover, to continue this research, analyses can occur at the state and local levels to determine trends and gather information that can be used for policy change.

With academic performance and success being influenced by a multitude of factors, such as socioeconomic status, belonging to an ethnic and/or racial minority, parental educational level, and the safety of both the school and community environment - there is a little priority placed on how community amenities that include the built environment impact school-aged youth's academic performance. Despite the NSCH capturing a few structural amenities, it must be noted that children living in neighborhoods with ample street lighting; well-maintained structural amenities (i.e., sidewalks); and, the presence of sidewalks, green space, playgrounds, crosswalks, community centers, and other youth-centered facilities are pertinent to childhood development.

The built environment has a profound impact on youth prior to them beginning primary school. With early childhood development, youth that live in communities with limited resources are more prone to be experience behavioral health issues and encounter developmental disabilities. These same problems that arise during early childhood can also appear at any point during childhood and adolescence due to the built environment. Because of this and the outcome it has on school engagement and academic success, there is a need for further research, program planning and implementation, and policy change on approaches to increase community amenities and improve the built environment while allowing residents to have a voice and have buy-in.

Addressing the built environment and the lack of protective and positive community amenities in a neighborhood or community is essential in breaking the perpetuating cycle that creates health disparities among children and adolescents. As indicated in Figure 1, neighborhoods with poor conditions and/or limited amenities in the built environment have a greater likelihood of having crime, violence, and community trauma due to both the crime and violence. Youth are just as likely to be victims of crime or violence in their neighborhoods and to develop PTSD and other signs of trauma. The trauma and PTSD is a form of behavioral and mental health that leads to disruptions in the classrooms and school settings among youth – posing a risk for grade repetition, poor grades, and dropping out of school early.

With the decreased likelihood of graduation stemming from modifiable problems - such as the built environment - youth from the neighborhoods with inadequate amenities are more likely to have limited employment and career opportunities because they do not possess a high school diploma. Because of the limited career opportunities, there will also be limited income and capital for the individual, which promotes poverty among the individual and family level. At the neighborhood and community level, this reduces the capital in the area – resulting in limited investments, upgrades, and improvements to the community. For example, rather than the addition of parks and grocery stores or repairing cracked sidewalks and reducing blight, there will be the continuous presence of dilapidated housing, graffiti, litter, pawn shops, and liquor stores. The latter is what begins the cycle again in terms of poor neighborhood conditions, which impacts another generation of youth.

There are several limitations to this study. First, the measure of school engagement is based on the perception of the parent/guardian. The operationalization of the NSCH definition of school engagement does not include quantitative data on how often a child completes

homework or the duration of homework and studying. The same can be said about whether a child cares about their schoolwork – a component of the school engagement variable in the dataset. Additionally, there is potential of bias with parents self-reporting is an issue as it cannot be validated. Moreover, the questions included in the NSCH survey are ones that are not necessarily indicative of poor community characteristics. For instance, the question of whether sidewalks are present in a neighborhood, does not equate to a neighborhood or community being in disarray or having negative community characteristics. In some cases, affluent neighborhoods and communities do not have sidewalks present; however, those neighborhoods have other amenities not captured in the survey that serve as protective factors for youth – indicating that there are culminating factors that impact school engagement among youth. Lastly, survey data for the NSCH were collected in a cross-sectional manner.

CONCLUSION

The study, despite its limitations, adds to a growing body of literature that highlights the influence of the built environment on childhood development. Children who care about doing well in school and complete their homework often perform better in future academic and professional careers. Using data from a nationally representative survey, this study examined the relationship between community characteristics - specifically, residential neighborhood amenities and detracting elements - and school engagement among US school-aged children. The availability of community amenities, such as presence of sidewalks and/or walking paths; presence of park or playground; presence of a recreation center; and, the presence of a bookmobile or library had a positive association with overall high school engagement. Similarly, the presence of negative and risky community characteristics, such as the presence of graffiti, litter, and abandoned homes were found to increase the likelihood of poor school engagement among school-aged youth. It must be noted that this study was observational and utilized a secondary data analysis for sample that reflected the entire United States. Future studies conducting a longitudinal survey would be useful to see if findings would be similar to those in this study.

Chapter 63

INVISIBLE THREATS: LEGAL METHODS TO ADDRESS ASTHMA TRIGGERS IN RENTAL HOMES

Prathyusha Chenji*

School of Law, Emory University, Atlanta, Georgia, USA

ABSTRACT

Federal housing laws dictate certain fundamental rights for tenants living in federally subsidized housing. Most state jurisdictions acknowledge a tacit “implied warranty of habitability” provision in residential lease agreements, which enforces the duty of landlords to fix defects on properties to ensure that rented living spaces are habitable for tenants and comply with local housing codes. Yet these legal baseline standards have not effectively secured healthy and safe living conditions for low-income, minority families. Environmental health hazards found in substandard housing, such as mold, lead, dust mites, and rodents serve as asthmatic triggers for children. When these health risks are eventually identified as triggers for their child’s ill health, parents may still forgo opportunities to confront their landlord for fear of retribution in the form of increased rent, penalties, or eviction. The scope of this project is to develop a resource that would facilitate a “know your rights” education for vulnerable families, offering guidance on how to negotiate with landlords for better housing conditions. The primary goal is to create an educational legal worksheet for families renting substandard housing and to guide them in seeking resources and relief to improve their living environment. This project strives to empower families by developing a resource that raises awareness, facilitates making housing rights more accessible, and highlights legal tools to help address asthmatic triggers within the home, thereby improving the health of vulnerable children.

INTRODUCTION

Substandard housing environments have a significant connection to pediatric asthma morbidity and present persistent challenges for low-income, minority families particularly [1,

* Corresponding Author’s Emails: pjchenji@gmail.com; jmarshall32@gsu.edu.

2]. Racial, ethnic, and income disparities in housing stock have deep roots in the history of American law and commerce. Through the middle of the twentieth century, some housing developers embedded private legal covenants in deeds to prevent sale of single-family homes to minority families [3]. Early federal housing initiatives incorporated government regulations, zoning restrictions, and lending policies to intentionally favor accommodating middle or higher-income, white households over low-income, minority communities [4, 5]. With the enactment of the Fair Housing Act of 1968, the federal government has established numerous public programs, policies, and incentives to help create better housing options for minority communities, including home ownership available to low-income and minority buyers [6]. Still, current trends suggest there remain marked disparities in home ownership rates among householders who identify as both low-income and minorities [7].

Subsidized rental housing initiatives have created affordable rental housing options for minority and low-income candidates [6], however, prominent zoning, tax, and financial policies in the United States strongly favor development of owner-occupied housing and make renting costly for tenants [8]. Even where low-income, minority families qualify for the US Department of Housing and Urban Development's Section 8 Housing Choice Voucher program, the promise of finding a better place to live may never materialize for many low-income renters. Vouchers are often difficult to secure through sporadic lotteries, and redistribution of poverty and racial segregation in suburban neighborhoods continue to disadvantage low-income and minority renters [6, 8]. The effect of these skewed dynamics on renting is that many low-income families must compete for relatively few affordable housing units, especially after the housing bubble surrounding the Great Recession of 2008. In 2016, a National Low-Income Housing Coalition study found that supply of affordable housing for low-income renters fell 7.2 million units short of demand [9].

Where tenants are able to secure rental accommodations, they must contend with whims and requirements of landlords who understand that affordable housing is scarce and demand from low-income families is high. Black and Hispanic tenants are more likely than white tenants to be cost burdened, with at least half of their income funneled into rent payments and little budget for necessities like food or healthcare [10]. Threat of eviction is also a reality that many tenants face if they fail to comply with a landlord's expectations. Formal evictions are generally the product of rent nonpayment, but many landlords also practice undocumented, informal evictions, where they change the locks to ensure tenants cannot return [11]. Low-income black and Latina female tenants, especially single mothers heading households with children, face higher rates of eviction than men or adult-only families [11].

A single eviction on tenants' records could classify them as problematic, resulting in their future housing applications being rejected and preventing them from securing quality housing for their children [11]. Ultimately, low-income, minority communities facing increased levels of forced displacement within the renters' market suffer tremendously in terms of decreased financial health and quality of life in pursuit of housing accommodation. Low-income and minority tenants are increasingly relegated to substandard housing options: black tenants are 1.7 times more likely to live in substandard housing, while low-income families are 2.2 times more likely occupy such spaces, often as a trade-off for keeping food on the table or ensuring a roof over their children's heads [12].

Substandard housing is broadly defined as a dwelling with moderate to severe physical defects which may contribute to adverse health effects or threaten the safety of individuals [13]. Evidence of the relationship between housing deficiencies and health effects has

previously been established, including studies which proved that interventions targeting housing defects improved householder health [13-18]. Examples of defects in substandard homes which may threaten the health of householders include physical conditions like inadequate ventilation, temperature exposure, low air quality or biological conditions such as pests, cockroaches, mice, mold, and other allergens [13]. Since low-income, minority families disproportionately occupy substandard housing, often in high poverty, predominantly minority neighborhoods, these populations may suffer heightened exposure to these defects [12, 19, 20]. One of the most prevalent diseases linked to substandard housing defects is childhood asthma. Increased asthma morbidity, hospitalizations, and mortality have been identified among low-income, minority children exposed to in-home, deteriorating housing defects [13, 19, 21].

Asthma is a common chronic disease in children. Exposure to asthma triggers and allergens within the home is strongly linked to asthma diagnosis, exacerbation, and morbidity in children in locales with substandard housing [15, 22, 23]. Children who live in substandard housing have higher sensitization to allergens, as well as increased exposure to asthmatic triggers such as mold, cockroaches, rodents, pet dander, cigarette smoke, and strong fumes or odors [2, 22].

Tenants encounter at least two challenges when attempting to address substandard housing conditions. First, tenants do not immediately recognize that deficiencies within a rented unit may be contributing to adverse health effects, lacking the knowledge to identify in-home asthma triggers [24]. Second, tenants also may not be aware of the legal rights and remedies which entitles them to have the issue mitigated or resolved [25]. Fear of eviction and landlord retaliation also contributes to tenant inaction [24, 25]. Unfortunately, there are too few legal tools available to low-income, minority tenants that educate and promote access to justice in landlord-tenant issues.

In most housing or landlord-tenant cases, the first step in a legal process is to survey the tenants' residence to identify issues for potential legal claims. If tenants can ensure a landlord takes responsibility for substandard housing, then the process could prove both educational and empowering. However, trying to understand the various aspects of the legal rights and due process may be overwhelming for non-lawyers, particularly low-income tenants who have few alternate housing options and fear retaliation from the landlord. The concept of informing laypeople with no legal degree on how to fight for their rights is a challenging process. The "informed layperson" perspective is the lens through which this project was developed.

This project creates a resource in the form of a legal worksheet to inform and empower tenants who have recognized that they have asthma-related health hazards within the home but have not been successful in confronting or convincing the landlord to make the necessary changes. to tenants. In the event that the landlord cannot be contacted or does not simply agree to make the necessary repairs to address health hazards in the home, the worksheet comes into play.

This worksheet also provides tenants with access to local legal aid organizations. In the event that they meet certain qualifications, e.g., proof of low-income or nature of the case, these organizations may be able to connect tenants to a lawyer at little or no cost. A lawyer would then require tenants to analyze how much their child or family has suffered due to environmental hazard in the home and to a landlord's failure to perform repairs.

Although this worksheet lists generic advice on strategies directed to all potential clients in a landlord-tenant issue, the legal services listed are specific to Atlanta tenants. Apart from the local references, the worksheet, could prove beneficial for any tenant in a similar situation, regardless of geographical location. In addition to highlighting the advantages of seeking legal representation, it is a tool that orients tenants on how to prepare to be a more successful potential claimant and legal client. Finally, it challenges tenants to consider the legal recourse and damages they deserve for what their child has suffered due to the landlord's failure to address a hazardous home condition.

Tenants would then meet with the legal representative to help identify goals and potential options for recourse. When working towards legal redress, tenants are expected to make personal decisions about why or how they intend to seek legal help. Tenants may have several potential options, but the first step is helping householders realize and articulate what relief they might be able to secure in addressing the current living situation.

- Do the tenants want to break the lease? If so, a lawyer can help review the contract, work through communications with the landlord, identify conflicts which may arise, and discuss possibilities of investing in an alternate living situation.
- Do the tenants want to move, but would also consider moving to another property owned by the same landlord? If yes, a lawyer may help the tenant negotiate with a landlord, or consider location, affordability, and costs the landlord should waive given his failure to repair the current home.
- Do the tenants want to force a landlord to make repairs to the current home situation. In this case, a legal representative can assess expected fixes, enforce action from the landlord, and advise remedies that may be owed to the family for what they have endured. In some cases, a lawyer may choose to file a lawsuit on behalf of the tenant. In this way, seeking legal help in light of living in hazardous home conditions can be an advantageous decision.

THIS STUDY

By (a) researching applicable legal literature, (b) reviewing state and local laws in Georgia, and (c) interviewing local lawyers, this project distills information and considerations that are likely to be significant for tenants seeking available legal relief.

Georgia Housing Statutes and Local Ordinances

Landlord-tenant law is not uniform across the fifty states. Each state adopts and adjudicates its own landlord-tenant laws. Federal Fair Housing laws have nationwide application, but their focus on eliminating discrimination in certain housing-related matters. As a result, legal research pertaining to this project was focused on Atlanta, Georgia. Limiting the scope to a localized population allowed for working more closely with applicable laws in order to maximize the benefits of this resource for troubled tenants. State law contained in the Official Code of Georgia and local ordinances, such as the Atlanta Housing Code, DeKalb

County Property Maintenance Code, and Gwinnett County Code of Ordinances, sets forth laws governing housing conditions in the metro-Atlanta area. These laws also describe the landlords' duty to maintain habitable living spaces for their tenants and provide the legal backbone of any tenant's potential claim against a landlord.

Interviews with Housing Lawyers

Interviews with housing lawyers on housing and tenant issues and discussing the types of legal relief and housing rights available to potential clients helped detail how landlord-tenant issues resolve in real-time application. This understanding was crucial to creating a resource that would be beneficial to tenants.

Legal Literature

The Georgia Department of Community Affairs has a rich, comprehensive resource available to the public titled the "Georgia Landlord-Tenant Handbook," which furnishes a background for relevant law and basic tenant rights. This handbook also details various issues tenants may encounter [25]. This handbook provided a reliable tool against which to verify the information presented on the worksheet.

FINDINGS

Based on review of applicable Georgia laws and interviews with Georgia housing lawyers, this worksheet was drafted to provide Georgia tenants with a guide to key questions concerning putative in-home environmental health risks (see Figure 1). The worksheet helps tenants answer questions that are critical to evaluating whether and how to secure assistance from counsel. Additionally, there are opportunities to acquire legal services for free or low costs for low-income tenants who may qualify. This fact would be comforting to tenants who might not pursue a legal consultation for fear of the costs involved. The following are quotations directly from the worksheet, along with corresponding explanations.

1. WHY Should a Tenant Seek Legal Help?

The worksheet begins by orienting tenants to think about the rights to which they are entitled, starting with the basic legal provisions specific to the resident state. For example, under Georgia law, the landlord has the duty to maintain the premises. Landlords do not always do their job, but the tenant has certain essential rights.

The worksheet goes on to provide context for a situation which might require legal help. It addresses the tenant directly. The following quotations are from the worksheet:

"If you or a loved one is facing a health condition because of your housing situation, but your landlord fails to make repairs, you may have grounds for a legal claim. You always have options. Even when it seems like you do not. Think about what you want, work with a lawyer. Be ready to ask questions. Set Goals."

Healthy Rental Housing Know Your Legal Rights

WHY seek legal help?

Under Georgia law, the landlord has the duty to maintain the premises. *They don't always do their job. But you HAVE RIGHTS too.*

If you or a loved one is facing a health condition because of your housing situation, but your landlord fails to make repairs, you may have grounds for a legal claim.

You always have options. *Even when it seems like you don't. Think about what you want, work with your lawyer. Be ready to ask questions. Set Goals.*

1. Do you want to force the landlord to make repairs? *What are the expected fees? How can landlord make it up to you? Is a settlement possible? Would you want to file a lawsuit?*
2. Do you want to break the lease early? *What penalties are in your contract? How would your landlord react? Will there be moving costs?*
3. If the landlord owns another property, is moving there an option? *How is the new location? Is it affordable?*

WHEN to start prepping?

Start now. *If you have any doubt something might be hazardous, start documenting with pictures and/or written communications with landlord.*

The earlier the evidence begins, the more compelling your story becomes. *Reach out to a lawyer for a consultation. Is it an easy fix? Could it go to court?*

BETTER TO GET LEGAL HELP EARLY THAN TOO LATE!

WHAT to know?

Do NOT withhold rent! *Even if you think it would force landlord to make repairs, not paying rent will make you look like a bad tenant! You may also risk eviction.*

Being a model tenant will make your story credible.

You will need the following documents: *copy of lease, all landlord correspondence, proof of rent payments, receipts of repairs, doctor's visits, medical bills.*

WHO do you call?

Atlanta Legal Aid Society
Pulaski Courthouse (404) 524-5811
P.O. Box 10000 (404) 377-5381

Atlanta Volunteer Lawyers Foundation
Adams (404) 521-0790

Health Law Partnership (HELP)
Adams (404) 787-2005

Atlanta Bar Association Rental Service
Adams (404) 521-0777

HOW to be ready?

Take pictures. *Leaks, pest, feces, mold, carpet stains, everything.*

Put everything to landlord in writing. *i.e. don't ask for fixes in-person, text or email instead.*

Keep track of everything relevant to your story. *Ex: child's doctor visits, medical bills & inhaler costs, clothes purchased/thrown away due to pests, TV ruined due to pipe leak, food spoiled because of fridge mold, etc.*

Collect necessary documents.

WHERE to start?

Inform your landlord of the problem **IN WRITING**. *Instead of talking in-person, deliver a letter, keep a copy. Write a text, email, take a video, be creative! Point is, you have proof if your landlord says "I didn't know!"*

Provide your landlord a deadline along with the notice.

Start thinking about damages. *End goal is to get repaid for your suffering, but you have to be able to prove your side of the story.*

Break the Cycle©

CREATED BY PRATHYUSHA CHENJI

Figure 1. Legal worksheet for tenants.

The worksheet goes on to challenge clients to consider their options by relaying a list of possible end-goals that clients may want to pursue with the help of their lawyer. It also shares potential factors or consequences to consider with each goal:

1. “Do you want to break the lease early? What penalties exist in your contract? How would your landlord react? Will there be moving costs associated with breaking the lease early?”
2. “If the landlord owns another property, is moving there an option? How is the new location? Is it affordable? Do you trust the landlord enough to negotiate this situation with him?”
3. “Do you want to force the landlord to make repairs in your current living situation? What are the expected fixes? How can the landlord make it up to you? Can you negotiate? Is a settlement possible? Would you want to file a lawsuit?”

2. WHEN Should a Tenant Start Preparing for Legal Representation?

This section advises a tenant to “start now.” Even if tenants are not sure about getting legal help immediately, they can begin gathering key information and evidence documenting their story about the adverse health conditions their children have encountered, i.e., ‘the case’.

“If you have any doubt that something [in the home] might be hazardous, start documenting with pictures and/or written communications with the landlord.” “The earlier the evidence begins, the more compelling your story becomes. Reach out to a lawyer for a consultation. Is [your problem] an easy fix? Could it go to court? Better to get legal help early than too late!”

3. WHO Does the Tenant Call for Help?

A list of legal resources is provided, tailored to the potential client living in Atlanta, Georgia. This is the only section of the worksheet that is specific to a geographic location, and should be edited based on the target audience, i.e., population intended to be helped. Additional resources which may be included in this section are online tools, app details, and alternative language tools. Services listed include: Atlanta Legal Aid Society, Atlanta Volunteer Lawyers Foundation, Health Law Partnership (HeLP), and the Atlanta Bar Association Referral Service.

4. WHAT to Know?

This section highlights key considerations for seeking legal help. For example, it asks the tenant not to withhold rent from the landlord, even if she believes that it would force the landlord to make repairs. The reasoning behind this advice is that not paying rent may undermine the strength of the tenant’s case and, in certain states like Georgia, may cause the tenant to risk eviction.

This section also encourages tenants to be “model tenants” because it makes their story, or case, more credible in the eyes of third parties. Finally, it provides a list of documents that tenants should start collecting in preparation for their first meeting with a legal representative. “You will need the following documents: copy of lease, all landlord correspondence, proof of rent payments, receipts of repairs, doctor’s visits, medical bills.”

5. WHERE Does a Tenant Start the Process of Improving a Home Situation?

This section orients tenants on what to do immediately after recognizing health hazards:

“Inform your landlord of the problem in writing. Instead of relying on a verbal request, deliver a letter with receipt of delivery, and keep a copy. Write a text, email, take a video, be creative! The point being that it provides evidence of the request if the landlord says, ‘I did not know!’”

“Give your landlord a deadline along with the notice.”

“Start thinking about damages. The ideal end goal is to get repaid for your suffering, but you have to be able to prove your side of the story.”

6. HOW Does a Tenant Get Ready to Seek Relief?

This section advises tenants to be vigilant and deliberate in their actions from the moment they begin to notice a need for a potential fix in the home:

“Take pictures. Leaks, evidence of bugs or mice, mold, carpet stains, everything.”

This section also pushes a tenant to keep a record of every communication with the landlord in writing, and substitute in-person interactions with text or email at every possibility.

“Keep track of everything relevant to your story, e.g., child’s medical bills, inhaler costs, clothes purchased/thrown away due to pests, T.V. ruined due to pipe leak, food spoiled because of fridge mold, cleaning supplies to clean black mold off of walls, etc.”

“Collect necessary documents.”

DISCUSSION

This project aims to raise awareness among low-income, minority renters about environmental factors within rental homes that produce adverse health outcomes. Additionally, this project offers tenants guidance on how to work with their landlords to resolve housing defects. It uses a worksheet to educate the renter of the potential situations that may arise after a health hazard has been recognized in the home. The worksheet also seeks to advise tenants on how to communicate the existence of a defect with the landlord and the options tenants may have to seek legal help if the landlord fails to make necessary repairs.

The legal worksheet is directed toward tenants who have recognized health hazards within the home but are unsure on how to confront them. Most individuals do not immediately consider seeking legal help. In the best-case scenario, the job of the tenants’ lawyer is to encourage an action from a landlord that is favorable to the tenants. The resource created from this project attempts to diminish assumptions that getting a lawyer is “too big for such a small issue,” or acquiring a lawyer to be too expensive or inaccessible. The worksheet

accomplishes this by referring the potential client to local nonprofit legal clinics and consultation resources. There is need for a tool which informs tenants about their own rights, as well as the legal process and encourages tenants to take that first step in pursuit of remediation. This worksheet presents one such intervention for addressing this need.

For example, consider tenants who may have recognized a potential in-home asthma trigger but have not confirmed whether it has had a detrimental impact on their child's health. Here, the tenants may have doubts about whether a housing defect is an asthma trigger. Parents may also be uncertain as to how urgent the situation is. They may notice an unusual odor emitting from the A/C unit but may not realize it is an issue that warrants a landlord's attention or responsibility. As a result, tenants may not reach out to the landlord, may disregard the defect, or consciously decide to postpone a confrontation with the landlord.

Alternatively, consider tenants who may have identified and confirmed the existence of asthmatic triggers in the home which affect their child. Here, parents are certain because a physician has confirmed that the child's health condition is being triggered by certain indoor environments. For example: parents were informed that mold is an asthmatic trigger. After investigating, they discovered black colored, foul-smelling residue behind the A/C unit. They then immediately attempted to inform the landlord, and either did not receive a response, or the landlord refused to accommodate the request for timely repairs. In both of the above scenarios, tenants are likely not thinking about legal recourse as an option.

In the first hypothetical, even if the tenants had been thinking about getting a lawyer, they likely believed they did not have a claim. In this case, the legal worksheet would encourage tenants to begin documenting any repairs in the home with photographs and informing the landlord in writing. The important message is that it is never too early to document observations or concerns that might ultimately be helpful in the case of a legal claim.

In the second hypothetical, tenants have done what they can and have informed the landlord about the situation. A landlord has the duty to repair where a home situation proves hazardous or unlivable. In this case, fungal spores are health hazards which trigger asthmatic episodes in children, making an environment unsuitable for a child. When a landlord fails to act upon such a request, there is potential for a legal claim.

The worksheet does not show tenants how to force the landlord to make repairs. In a successful scenario, this outcome would be achieved by a lawyer. Instead, the legal worksheet familiarizes parents with guidance in preparing for a possible legal proceeding. Additionally, the legal worksheet encourages tenants to consider how best to maintain and manage a good tenant-landlord relationship. Tenants who are in good standing with their landlord and have all correspondence to the landlord in writing can best prove their assertions about adverse health conditions. For this reason, these tenants are more likely to be considered credible by a court or mediator. Therefore, if the tenants take prudent steps in preparing their claim, then tenants would have the best possible chance of securing an outcome in their favor.

The worksheet serves to accomplish more than simply providing tenants an opportunity to educate themselves about their rights and the legal process. It also serves to aid a lawyer with her job. A lawyer representing tenants requires a narrative upon which to build a case favorable to her client. By structuring the information in a "who, what, when, where, why, how" format, the legal worksheet encourages tenants to prepare by gathering information the lawyer may require. Once the narrative has been acquired, the lawyer has more time to counsel clients on viable options and work with clients to set goals. Overall, the interactions between a lawyer and clients are most efficient when both parties know what to expect. For

that reason, the legal worksheet seeks to guide tenants prior to consultation with a lawyer. An efficient lawyer-client team is most effective in providing a greater chance for tenants to win the case and acquire damages for what their child has suffered.

Figure 2. Breaking the cycle of adverse health disparities relating to childhood asthma within substandard rental homes.

This project helps break the cycle of environmental health disparities by providing an intervention to childhood asthma morbidity among low-income and minority families renting substandard housing options (see Figure 2). Once residential exposure to health hazards have been recognized and tenants have confirmed that these environmental triggers pose a serious threat to their child's asthmatic condition, this resource educates tenants of their rights and empowers them to consider legal recourse. After tenants consult with a lawyer, they are in a better situation to confront the landlord to make necessary repairs within the rented unit. If successful, a child within the home experiences decreased exposure to environmental, asthma triggers and improved health outcomes.

RECOMMENDATION: FRAMEWORK FOR APPLICATION OF LEGAL WORKSHEET

The sample worksheet can be made available to users either in paper or electronic form. The worksheet is designed as a resource for families renting substandard housing units from unresponsive landlords. If distributed among tenants living with hazardous home conditions, the worksheet should enable and empower tenants to consider how to proceed and how to consider legal recourse. By encouraging action to remediate indoor hazardous conditions, and thereby decreasing exposure to asthmatic triggers, this worksheet would be a cost-effective intervention for preventing childhood asthma.

The worksheet may be suitable for distribution in environments like children's hospitals, community schools, or legal clinics. Health provider offices may distribute the worksheet as

an informational resource to parents after recognizing that a home environment might be worsening a child's asthmatic condition. Public health nurses performing in-home visits, social workers and community organization that work with children with asthma could also use the worksheet. The worksheet may also be made available in schools or day care centers where parents would expect to receive other educational resources. Legal aid clinics may share this resource with potential clients during an initial consultation regarding hazardous home conditions. This resource would be the most impactful if available online to tenants who may be researching their children's health or in-home living environment. Social media provides another channel that could help make the content from this worksheet widely accessible to the public as an educational resource. The content can be creatively organized into interactive videos or online platforms. Additionally, the content can be expanded for inclusion in an educational handbook or tutorial.

CONCLUSION

Once parents who are renting homes in low income neighborhoods have recognized that indoor environmental risk factors affecting children's health may be present within the home, it is time to act. The legal worksheet aims to educate tenants to be vigilant and to prepare for possible legal support as soon as they are aware of potential health risks. Where tenants are in a compromised living situation and cannot rely on their landlord to address and reduce environmental health hazards, the worksheet lays out the "who, what, when, where, why, how" of seeking a legal solution. The worksheet presents an overview of information and advice for tenants to consider prior to securing a lawyer. It also provides low income families with a list of legal resources in their geographic area (in this case, local Atlanta resources). The intent of this worksheet is that it demystifies how legal services could resolve landlord-tenant issues, improve living situations among low-income renters, and improve and maintain children's health.
